

Contrasting Neurofunctional Correlates of Face- and Visuospatial-Processing in Children and Adolescents with Williams Syndrome: Convergent Results from Four fMRI Paradigms

Madeline H. Garvey, Tiffany Nash, J. Shane Kippenhan, Philip Kohn, Carolyn B. Mervis, Daniel P. Eisenberg, Jean Ye, Michael D. Gregory, Karen Faith Berman

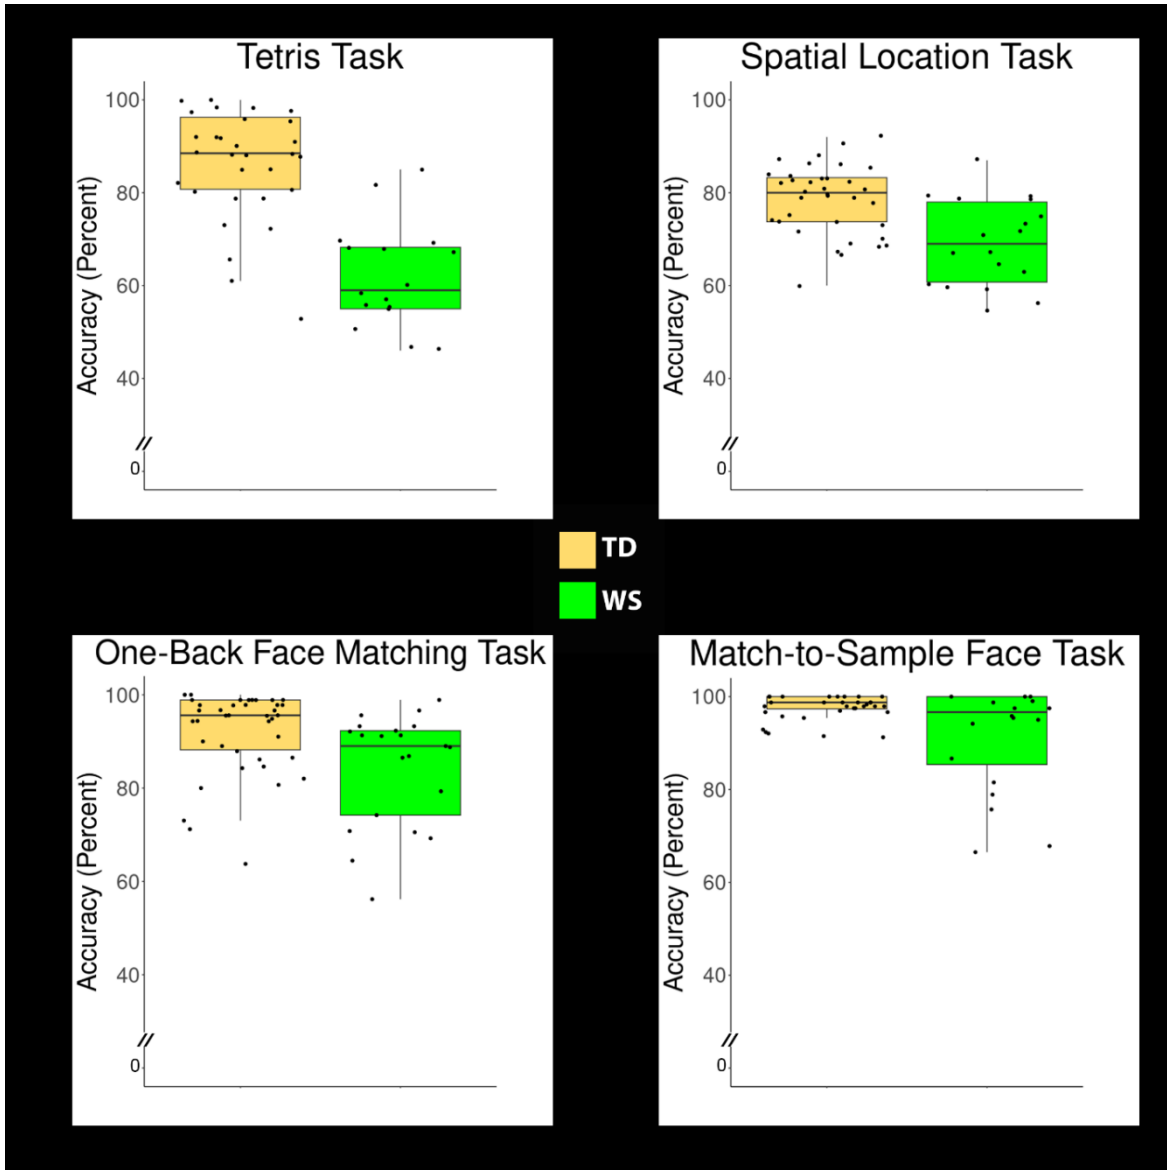

Included Supplementary Information:

Supplementary Figure 1	Functional activation by task in typically developing individuals and people with WS	Page 2
Supplementary Figure 2	Performance accuracy for all participants during each of the four fMRI task	Page 3
Supplementary Table 1	Clusters showing significant activation in each group and between-group differences for the Match-to-Sample Face Task	Page 4
Supplementary Table 2	Clusters showing significant activation in each group and between-group differences in the One-Back Face Matching Task	Page 5
Supplementary Table 3	Clusters showing significant activation in each group and between-group differences in the Spatial Location Task	Page 6
Supplementary Table 4	Clusters showing significant activation in each group and between-group differences in the Tetris Task	Page 7
Supplementary Table 5	Partial correlation coefficients between age, IQ, sex and performance separated by task	Page 8

Supplementary Figure 1. Functional activation by task in typically developing individuals and people with WS. **Top two rows:** activation patterns shown separately for each of two visuospatial tasks within TD individuals (left column) and within people with WS (middle column), as well as between-group activation difference maps for each task (right column). For each visuospatial processing task, TD individuals and people with WS activated the dorsal stream and, in particular, the bilateral intraparietal sulci, with more robust engagement seen in TD individuals (blue voxels in the between-groups analysis). **Bottom two rows:** activation patterns shown separately for each of two face processing tasks within TD individuals (left column) and within people with WS (middle column), as well as between-group activation difference maps for each task (right column). For each face processing task, both groups (TD individuals and people with WS) activated the ventral stream and, in particular, the bilateral fusiform gyri, with more robust engagement in particular fusiform areas in children and adolescents with WS (red voxels in the between-groups analysis). Activation maps are shown thresholded at $p < 0.05$, family-wise error corrected.

Supplementary Figure 2: Performance accuracy for all participants during each of the four fMRI tasks. Dots represent accuracy for each individual, boxes represent the range of the central 50% of data, and whiskers represent the spread of the maximum and minimum values for each group within 1.5x the interquartile range. TD=typically developing individuals, WS=individuals with Williams syndrome.

Supplementary Table 1. Clusters showing significant activation in each group and between-group differences for the Match-to-Sample Face Task (BA = Brodmann Area)
