Abstract

This is the latest version of the Global VAR (GVAR) dataset. The GVAR is a global modelling framework for analyzing the international macroeconomic transmission of shocks, taking into account drivers of economic activity, interlinkages and spillovers between different countries, and the effects of unobserved or observed common factors. This dataset includes quarterly macroeconomic variables for 33 economies (log real GDP, y_{it} , the rate of inflation, dp_{it} , short-term interest rate, r_{it} , long-term interest rate, lr_{it} , the log deflated exchange rate, ep_{it} , and log real equity prices, eq_{it}), as well as quarterly data on commodity prices (oil prices, $poil_t$, agricultural raw material, $pmat_t$, and metals prices, $pmetal_t$), over the 1979Q2 to 2016Q4 period. These 33 countries cover more than 90% of world GDP. You can download the data, as well as a description of the compilation, revision and updating of the GVAR Database, from the [Faculty of Economics, University of Cambridge website](#). It would be appreciated if use of the updated dataset could be acknowledged as: “Mohaddes and Raissi (2018). *Compilation, Revision and Updating of the Global VAR (GVAR) Database, 1979Q2-2016Q4*. University of Cambridge: Faculty of Economics (mimeo)”.

*We are grateful to Paul Cashin, Alexander Chudik, M. Hashem Pesaran, and Vanessa Smith for their helpful comments and suggestions. Part of this work was conducted while Kamiar Mohaddes was a Visiting Scholar at IMF’s Asia and Pacific Department in September 2017. The views expressed in this document are those of the authors and do not necessarily represent those of the International Monetary Fund or IMF policy.

[†]Corresponding author. Email address: km418@cam.ac.uk.

Introduction

This is the latest version of the Global VAR (GVAR) dataset. It extends up to 2016Q4 the last available GVAR dataset (the ‘2013 Vintage’), available from the [GVAR Toolbox webpage](#), which was prepared by Rodrigo Mariscal, Ambrogio Cesa Bianchi and Alessandro Rebucci at the Inter-American Development Bank, Washington DC, US. This updated dataset (1979Q2-2016Q4) will be referred to as the ‘2016 Vintage’, and was prepared by Kamiar Mohaddes (University of Cambridge) and Mehdi Raissi (International Monetary Fund). The 2016 Vintage is largely obtained by extrapolating forward (using growth rates) the data of the 2013 Vintage from 2013Q2 to 2016Q4. The construction of the 2016 Vintage is based on data from Haver Analytics, the International Monetary Fund’s International Financial Statistics (IFS) database, and Bloomberg.

Table 1: Countries in the GVAR Model

Asia and Pacific	North America	Europe
Australia	Canada	Austria*
China	Mexico	Belgium*
India	United States	Finland*
Indonesia		France*
Japan	South America	Germany*
Korea	Argentina	Italy*
Malaysia	Brazil	Netherlands*
New Zealand	Chile	Norway
Philippines	Peru	Spain*
Singapore		Sweden
Thailand	Middle East and Africa	Switzerland
	Saudi Arabia	Turkey
	South Africa	United Kingdom

Notes: * indicates that the country is included in the euro area block.

The GVAR is a modelling framework of the world economy designed to explicitly model economic and financial interdependencies across markets and countries at national and international levels, and was originally proposed by [Pesaran et al. \(2004\)](#) and further developed by [Dees et al. \(2007\)](#). It links individual country-specific models in a coherent manner to form a global modelling framework by using time series, panel data, and factor analysis techniques. It has been used in bank stress testing, the analysis of China’s growing importance for the rest of the world economy ([Cesa-Bianchi et al. 2012](#) and [Cashin et al. \(2016, 2017b\)](#)), the international macroeconomic transmission of weather shocks ([Cashin et al. 2017a](#)), the impact of commodity price shocks (see [Mohaddes and Pesaran \(2016, 2017\)](#) for the global

macroeconomic consequences of country-specific oil-supply shocks and [Cashin et al. 2014](#) and [Mohaddes and Raissi 2015](#) for the differential effects of demand- and supply-driven commodity price shocks), and other real and financial shocks (see, for instance, the GVAR handbook edited by [di Mauro and Pesaran 2013](#) for empirical applications from 27 contributors), as well as in forecasting (see [Pesaran et al. 2009](#) and [Bussière et al. 2012](#) for the earliest GVAR forecasting applications to the global economy). For an extensive survey of the latest developments in GVAR modelling, both the theoretical foundations of the approach and its numerous empirical applications, see [Chudik and Pesaran \(2016\)](#).

The GVAR dataset includes quarterly macroeconomic and financial variables for 33 economies (log real GDP, y_{it} , the rate of inflation, dp_{it} , short-term interest rate, r_{it} , long-term interest rate, lr_{it} , the log deflated exchange rate, ep_{it} , and log real equity prices, eq_{it}), as well as quarterly data on commodity prices (oil prices, $poil_t$, agricultural raw material, $pmat_t$, and metals prices, $pmetal_t$), over the 1979Q2–2016Q4 period. These 33 countries cover more than 90% of world GDP, see [Table 1](#). You can download the data from the [Faculty of Economics, University of Cambridge webpage](#) or the [GVAR Toolbox webpage](#). This data can be used to estimate GVAR models using the GVAR Toolbox (see [Smith and Galesi 2014](#) for details) or to estimate individual country VARX* models (as is done in [Burney et al. 2018](#), [Esfahani et al. \(2013, 2014\)](#) and [Mohaddes and Raissi 2013](#)).

It would be appreciated if use of the updated dataset could be acknowledged as: [Mohaddes, K. and M. Raissi \(2018\)](#). *Compilation, Revision and Updating of the Global VAR (GVAR) Database, 1979Q2-2016Q4*. University of Cambridge: Faculty of Economics (mimeo).

Real GDP

For compiling the 2016 Vintage Real GDP, seasonally-adjusted IFS data were used (Concept: GDP Volume Index, Quarterly, 2010 = 100) for all countries with the exception of Brazil, China, and India. For Brazil and China seasonally-adjusted data from Haver Analytics were utilized (Brazil: Real GDP: Chained Index, 1995=100 and China: Real GDP, Billions of 2015 Yuan). The quarterly rate of change of the seasonally-adjusted IFS/Haver series was then used to extrapolate forward the 2013 Vintage GDP from 2013Q2 to 2016Q4.

For India (for which we replaced the whole series), seasonally-adjusted data from the Central Statistics Office/Haver Analytics was used (Concept: GDP at 2010 Prices and Exchange Rates) for the period 1996Q2-2016Q4. The quarterly rate of change of the Industrial Production General Index (from the Ministry of Statistics and Program Implementation/Haver Analytics) over 1979Q1-1996Q1 was used to extrapolate backward the real GDP data.

Consumer price index

In order to create the 2016 Vintage CPI, IFS data (Concept: Consumer Prices, All items, Quarterly, 2010 = 100) were collected for all countries with the exception of Argentina and India. For Argentina seasonally-adjusted data from Haver Analytics (Concept: Buenos Aires Consumer Price Index, Jul.11–Jun.12=100) was utilized.¹ The quarterly rate of change of the seasonally-adjusted IFS/Haver series was then used to extrapolate forward the 2013 Vintage CPI from 2013Q2 to 2016Q4.

For India (for which we replaced the whole series), seasonally-adjusted data from Labor Bureau of India/Haver Analytics (Concept: Industrial Workers Consumer Price Index, Apr 2001-Mar 2002=100) was used.

Equity price index

Updated equity price series are from Haver Analytics. Firstly, a quarterly MSCI share price index, excluding dividends, in local currency was collected for all countries. Secondly, the 2016 Vintage equity price index was obtained by forward extrapolation of the 2013 Vintage using the rate of change of the new series from 2013Q2 to 2016Q4.

Exchange rates

Exchange rate series are from IFS. A quarterly average of the nominal bilateral exchange rates vis-a-vis the US dollar (units of foreign currency per US dollar) was obtained for each country. The 2016 Vintage exchange rate was obtained by forward extrapolation of the 2013 Vintage using the rate of change of the new series from 2013Q2 to 2016Q4.

Short-term interest rates

IFS data are used for Austria, Argentina, Chile, China, Malaysia, and Turkey (Concept: Interest Rates, Deposit Rate); for Peru (Concept: Interest Rates, Discount Rate); for Canada, Belgium, France, Germany, Italy, Mexico, Norway, Philippines, South Africa, Sweden, UK and US (Concept: Interest Rates, Treasury Bill Rate); and for Australia, Brazil, Finland, India, Indonesia, Japan, Korea, Saudi Arabia, Singapore, Spain, Switzerland, and Thailand (Concept: Interest Rates, Money Market Rate). For the Netherlands and New Zealand, the 3-month government repo rate and the 30-days bank-bill yield were used, respectively. The 2013 Vintage short term interest rates are then extended with these series from 2013Q2 to 2016Q4. Note that for Germany, as the money market rate which was used in the earlier

¹The base year for Chile: CPI series is 2009.

vintages was no longer available, we used the 3-month treasury bill from 2010Q1 onward and for Singapore the overnight rate average was used from 2005Q3 onward.

Long-term interest rates

The IFS data (Concept: Interest Rates, Government Securities, Government Bonds) are used to extend the series for all countries except for India for which long-term interest rate data are available, namely Australia, Austria, Belgium, Canada, France, Germany, Italy, Japan, Korea, Netherlands, New Zealand, Norway, South Africa, Spain, Sweden, Switzerland, United Kingdom, and United States. The 2016 Vintage long-term interest rates are extended with these series from 2013Q2 to 2016Q4.

For India (for which the long-term interest rate was not included in earlier vintages of the GVAR dataset), the 10-Year Government Bond Yield (EOP, % per annum) from the Reserve Bank of India (RBI) over the period 1996Q2-2016Q4 was used. For the period 1979-1996, annual data from RBI was available, and used for interpolation.

Oil price index

For the oil price index a Brent crude oil price from Bloomberg was used (Series: Current pipeline export quality Brent blend. Ticker: CO1 Comdty). To construct the quarterly series, the average of daily closing prices was obtained for all trading days within the quarter. The quarterly rate of change of this new series was used to extrapolate forward the 2013 Vintage oil price index from 2013Q2 to 2016Q4.

Other commodities: Agricultural raw material and metals price indices

The agricultural raw material and metals price indices were both taken from the IMF's Primary Commodity Prices monthly data.² Monthly averages of the indices were taken for each quarter. The 2016 Vintage price indices were obtained by forward extrapolation of the 2013 Vintage using the rate of change of the new series from 2013Q2 to 2016Q4.

Construction of the variables

Log real GDP, y_{it} , the rate of inflation, dp_{it} , short-term interest rate, r_{it} , long-term interest rate, lr_{it} , the log deflated exchange rate, ep_{it} , and log real equity prices, eq_{it} , are six variables

²<http://www.imf.org/external/np/res/commod/index.aspx>.

included in most of the GVAR applications in the literature. These six variables are included in the dataset and are constructed as

$$\begin{aligned} y_{it} &= \ln(GDP_{it}), & dp_{it} &= p_{it} - p_{it-1}, & p_{it} &= \ln(CPI_{it}), & ep_{it} &= \ln(E_{it}/CPI_{it}), \\ r_{it} &= 0.25 \ln(1 + R_{it}^S/100), & lr_{it} &= 0.25 \ln(1 + R_{it}^L/100), & eq_{it} &= \ln(EQ_{it}/CPI_{it}), \end{aligned} \quad (1)$$

where GDP_{it} is the real Gross Domestic Product at time t for country i , CPI_{it} is the consumer price index, E_{it} is the nominal exchange rate in terms of US dollar, EQ_{it} is the nominal Equity Price Index, and R_{it}^S and R_{it}^L are short-term and long-term interest rates, respectively. In addition to the above variables the dataset also includes the log of oil prices, $poil_t$, the log of agricultural raw material prices, $pmat_t$, and the log of metals prices, $pmetal_t$.

Finally, for the convenience of VARX* modelling, we have also included the corresponding ‘star’ variables, $\mathbf{x}_{it}^* = (y_{it}^*, dp_{it}^*, eq_{it}^*, r_{it}^*, lr_{it}^*)'$ for each country, constructed using country-specific trade shares, and defined by

$$\mathbf{x}_{it}^* = \sum_{j=1}^N w_{ij} \mathbf{x}_{jt}, \quad (2)$$

where w_{ij} , $i, j = 1, 2, \dots, N$, are bilateral trade weights, with $w_{ii} = 0$, and $\sum_{j=1}^N w_{ij} = 1$. In the dataset w_{ij} is computed as a three-year average to reduce the impact of individual yearly movements on the trade weights. More specifically, the trade weights are computed as

$$w_{ij} = \frac{T_{ij,2012} + T_{ij,2013} + T_{ij,2014}}{T_{i,2012} + T_{i,2013} + T_{i,2014}}, \quad (3)$$

where T_{ijt} is the bilateral trade of country i with country j during a given year t and is calculated as the average of exports and imports of country i with j , and $T_{it} = \sum_{j=1}^N T_{ijt}$ (the total trade of country i) for $t = 2012, 2013, 2014$. Note that the trade flows, T_{ijt} , are also provided in a separate excel file for the 33 countries over the 1980–2016 period.

PPP - GDP data

The source for construction of the country specific PPP-GDP weights is the World Development Indicator database of the World Bank. The GDP in Purchasing Power Parity terms in current international dollars (Ticker: NY.GDP.MKTP.PP.CD) was downloaded for all countries from 1990 to 2016.

Trade matrix

To construct the trade matrices, the IMF Direction of Trade statistics was used. For all the countries considered the matrix of Exports and Imports (c.i.f.) was downloaded at the annual frequency. The data for 2013–2016 average of Exports and Imports are appended to the trade matrices associated with the 2013 Vintage.
