

Educational heterogamy during the early phase of the educational expansion: Results from a university town of Tartu, Estonia in the late 19th century

Abstract

BACKGROUND

In historical perspective, the transition from pre-industrial to modern societies is associated with increasing social status heterogamy. As individual's acquired characteristics became more important for partner selection than inherited class status, the importance of status homogamy declined and marrying outside one's own social group became more frequent.

OBJECTIVE

We investigate educational heterogamy in a university town at the eastern border of the Hajnal line at the end of the 19th century. We ask whether marriage of unequally educated partners is related to dissimilarity in other characteristics of the partners. Ethnic background, origin (place of birth) and age difference between the spouses are considered as characteristics that may associate with sorting into educationally heterogamous unions.

METHODS

The analysis uses data from the 1897 census in Tartu. Using logistic regression models, we estimate how age difference, origin heterogamy, and ethnic heterogamy of the spouses is associated with the probability of educational heterogamy.

RESULTS

The results indicate a positive relationship between educational heterogamy and marrying outside own ethnic or origin group, but no effect for spousal age difference.

CONCLUSIONS

Our study provides new evidence about marriage markets during modernisation, more specifically about the role of education. We show that educationally heterogamous unions in Tartu were also more often heterogamous in terms of partners' background characteristics. This suggests that education may have motivated intermarriage by ethnicity and origin.

CONTRIBUTION

Previous literature on this period has focused on social homogamy based on occupational information, while research on educational assortative mating mostly exists for the second half of the 20th century and later. We contribute by studying the importance of education in marital selection in the early phase of the educational expansion and economic modernisation.

1. Introduction

Pre-industrial societies are usually described as having relatively closed social groups with limited possibilities for mobility between them. The prevalence of social homogamy is considered as evidence of such barriers between different social strata (Bras and Kok 2005; Dribe and Lundh 2005), meaning that it is not easy to improve social status by “marrying up”. Historical perspectives of social mobility through marriage are relatively well studied in West European countries, mostly using occupational data (Leeuwen and Maas 2010; 2019). Also, marriage as a demographic subject has long been researched in Western countries (e.g. Hajnal 1953). In Eastern Europe, despite some early inquiries of this topic (e.g. Chojnacka 1976; Sklar 1974), development of data sources and research has been relatively modest compared to the scholarship in the West (Wetherell and Plakans 1997). At the same time, East European countries locating at the border of a large demographic divide have a potential to provide interesting insights to family and marriage systems, as shown by some more recent studies (Liczbińska 2012; Szoltysek 2007). The mentioned divide is the Hajnal line, placed between St. Petersburg in Russia and Trieste in Italy. This imaginary line designates the eastern border of the area that historically experienced the European marriage pattern (Hajnal 1965; 1982). The European marriage pattern associated with a relatively high age at marriage and large proportions of adults who remained single, both of which had significant implications for fertility and demographic transition.

In this article, to extend the geographical horizon of marriage patterns research and to gain insights into the importance of education in marital selection at the time, we investigate educational heterogamy in the late 19th century Tartu, Estonia. Estonian territory, then divided between the provinces of Livland and Estland of the Tsarist Empire, remained to the west of the Hajnal line. It was among the few areas of the Empire that, in the sense of demographic development, followed trajectories similar to North-Western Europe. From at

least the end of the 18th century Estonian nuptiality had the characteristics of the European marriage pattern (Palli 1984, 1988) and Estonia experienced one of the earliest fertility transitions in Europe (Coale, Anderson and Härm 1979; Coale and Watkins 1986; Gortfelder and Puur 2019; Katus 1994). Tartu was not one of the largest towns in the region but due to the presence of a university and a number of secondary schools it had a unique importance in the region. This led to a comparatively diverse population consisting of different educational, social, ethnic, and religious groups (Berendsen and Maiste 1999). Because of this population heterogeneity Tartu is an excellent setting to study social heterogamy in the late 19th century.

Our main research question is whether educational heterogamy was more likely if one married outside of his/her origin (place of birth), ethnic or age group. We use individual-level data from the first imperial census of Russia in 1897, which was carried out in Tartu in a particularly detailed manner (Berendsen and Maiste 1999). Our findings suggest that educational heterogamy was more often the characteristic of couples in which the spouses originated from different origin and ethnic backgrounds. This result speaks about the potential importance of formal schooling in the 19th century urban marriage market.

2. Background and research questions

Social heterogamy during modernisation

While modern partnerships are considered mostly as romantic relationships, traditional marriage associates less with individuals' own will, or affection, and more with kinship interests or obvious socio-economic gains from marriage (Cherlin 2004; Coontz 2004, 2006). Formation of a new marital union provided opportunities to widen social networks, increase wealth or enlarge land holdings. This made marriage and partner choice a strategic question and an object of social pressure (Leeuwen and Maas 2005, 2010; Dribe and Lundh 2009).

Sociological literature has considered partner choice to be constrained by three main factors: the structure of the marriage market, social influences, and the individual's own preferences. The first refers to the availability of marriageable partners and means that marriages between different social groups are less frequent if group sizes are very different. The two other factors, however, pertain to forces that guide one in choosing a spouse. Social pressure from the community or family could influence people to find a partner from the same religion or same geographical area (Kalmijn 1998).

Partner choice in pre-industrial times was critical because of the role that social status played in a success or failure of an individual. Socio-economic status was the primary predictor of welfare and access to resources (Bengtsson, Campbell, and Lee 2004). Status was often inherited or attached to the ownership of inheritable resources such as land. In this context, marrying someone from a higher class, higher social status, or simply from a wealthier family, was one of the few opportunities for upward mobility. Conversely, marrying an individual from a lower social status implied a risk of downward mobility (Dribe and Lundh 2005). In short, partnering someone from the same social group was a common strategy to maintain or improve status, while partnering with lower stratum entailed considerable risks. Because of this, marriages tended towards social endogamy, which in turn maintained the relative social immobility in pre-industrial societies (Bras and Kok 2005; Bull 2005; Dribe and Lundh 2010; van Leeuwen and Maas 2002).

According to the industrialisation thesis, modernisation favoured status attainment through individual achievement and reduced the relevance of previously important ascribed characteristics (Treiman 1970). Similarly, the status-attainment hypothesis argues that with changes in the labour market, individuals' achieved characteristics, such as occupation or education, become more important in partner selection than the ascribed characteristics, e.g. social class of origin (Smits et al. 1998). Empirical findings supporting these theories have

demonstrated clear shifts in partner formation as modernisation progressed (Zijdeman and Maas 2010). Taking a collective approach to study social homogamy in the past, the authors of a special issue in *The History of the Family* demonstrated that men's own occupational status becomes more important over parental status in the second half of the 19th century and this shift occurs similarly across different historical communities, for example in the Netherlands, Belgium and Hungary (Lippényi et al. 2019; Maas and van Leeuwen 2019; Van Leeuwen et al. 2019). On the other hand, in France, parental status homogamy remained the same during the 19th century (Maas et al. 2011). In some countries, industrialisation may have started a decline of social homogamy among rural population, but the economic pressure of societal change supported the tendencies to protect against resource dilution and thus marry homogamously by social class, like in Norway (Bull 2005) and Finland (Roikonen and Häkkinen 2019). Such, somewhat contradictory effects of modernisation are probably expected among rural populations since the latter generally had a more limited access to education and new occupations compared with towns. In relation to that, social or occupational class (often based on landownership) probably remained strong factors of marriage market in the countryside, whereas we would expect that education as a mate selection criterion strengthened first in towns where more opportunities existed to capitalise on formal schooling.

As it becomes obvious from the above cited literature, occupation is often the key status variable in historical social homogamy literature. Education has not received so much attention, partly because historical data sources favour occupational data (Leeuwen and Maas 2010). But also due to the fact that educational expansion and the increase in the role of education as a predictor of income mainly happened in the 20th century. Literature on educational assortative mating demonstrates a long-term interest in the issue (see Michielutte 1972) but analyses of assortative mating typically consider periods since the mid-20th

century (Rockwell 1976; Kalmijn 1991a; Mare 1991; Smits, Ultee and Lammers 1998; Schwartz and Mare 2005). Less is known about the earlier period of educational expansion, when the changing educational distribution began to affect the balance of educational homogamy (Michielutte 1972). Considering that educational aspects of the 19th century social homogamy are understudied, in this paper we try to fill some of this gap by focusing on assortative mating of the modernisation period. As suggested above, it would be more difficult to address this question in a rural context. In a town, however, it is more likely that education emerged quite early as a predictor of economic success and therefore was an important factor of marital selection. Education could be especially important in a town like Tartu, as we will describe in the next section.

Besides choosing a spouse by occupation or education, heterogeneity of urban populations generally implies other potential variability in partner characteristics. The urban setting of the modernisation period was influenced by influx of migrants from rural areas and, in many cases, also from abroad, and this affected partner choice and family formation (Moreels and Matthijs 2010; Schumacher, Matthijs and Moreels 2013). In Finland, the more urbanised or industrialised regions were more likely to have higher levels of heterogamy (Roikonen and Häkkinen 2019). Similarly, in France, partner formation in cities was less homogamous by parental status (Maas et al. 2011). On the one hand, it has been found that migrants generally were disadvantaged on the urban marriage market, since urban born individuals preferred to marry within their own group (van de Putte 2003). Migrants usually faced adaptation problems, which made finding a partner difficult, although this may have varied depending on the country (Puschmann et al. 2014).

Sociological and historical research generally agree that people prefer a partner who is ethnically, religiously, and culturally similar (Kalmijn 1998; Mare 1991; van Leeuwen and Maas 2005), which may add to the disadvantage of migrants from abroad. It is also known

that spouses became more similar in age during modernisation (Dribe and Lundh 2009; van Poppel et al. 2001). Age heterogamy in the pre-industrial period was explained by the importance of wealth prior to marriage and patriarchal relationships in the family, which favoured older men (Beekink, Liefbroer, and van Poppel 1998). Decrease in age can be interpreted as a decline in the importance of property related social status and increase in affection related characteristics (Dribe and Stanfors 2017; van Poppel et al. 2001). The latter could be a supporting factor of educational homogamy, because equally educated individuals are more likely to share similar values (Kalmijn 1991b).

To summarise, the modernising urban setting of the 19th century may have brought about unprecedented opportunities for choosing a spouse from a different social group. On the other hand, individual preferences to marry someone culturally similar (“like marries like”) may have even increased, as also demonstrated by the rising age homogamy. At this point, it is relevant to ask how these opposite factors shaped the marriage market. Was marrying someone from a different cultural background motivated by potential gains from the partner’s education? Before formulating our hypotheses about this, we first describe the context of the late 19th century Tartu.

Population of the late 19th century Tartu

At the time, the territories of modern-day Estonia and Latvia were divided into the three provinces of Estland, Livland and Kurland, which together made up the Baltic provinces of the Tsarist Empire. They were to a large degree autonomous from the central authorities in St. Petersburg, as well as ethnically, linguistically and religiously different from Russia proper. Culturally the provinces were more intertwined with the German or Protestant cultural space. Local political, economic and cultural life had been dominated by the Baltic Germans already since 13th century, although they constituted only a small proportion of the

total population (5%). In the countryside Estonians (in Estland and Northern Livland) and Latvians (in Southern Livland and Kurland) were the ethnic majority. In urban areas, the proportions of Estonians (or Latvians) and the Baltic Germans were more similar (Berendsen and Maiste 2005, pp 128–132).

This traditional setting started to unravel in the second half of the 19th century. Economic modernisation brought about industrialisation and while the development of industry was far behind that of Western Europe, Estland and Livland still became one of the more industrialised areas in the Tsarist Empire. Tartu, however, was little affected by this. With regard to heavy industry there was only one factory, specialising in agricultural machinery, and a gas plant that mainly supplied the town. In total there were only about a thousand industrial workers in Tartu at the end of the nineteenth century and the town preserved more of its merchant-artisanal outlook than the new industrial centres. Still, artisans did become a part of larger businesses instead of owning their own businesses, as was the norm beforehand (Palamets 2005; Rosenberg 2010, p 163).

In terms of educational development, the Baltic provinces already had achieved full literacy by the 1881 census, which is very early by European standards (Kasekamp 2010, p. 85; Raun 1979). This was related to the dominant role of the Lutheran Church and its teachings that prioritised the ability of individual believers to read scripture. Tartu had an important role in these developments, since it was clearly the main educational and cultural centre in the provinces. This was due to the presence of a number of secondary schools, the only classical university in the provinces, a teachers' seminary, and the scientific and cultural societies that revolved around them (Berendsen and Maiste 1999, pp. 166–172). This means that in Tartu differences in schooling were about the level of education and not simply literacy.

There was a considerable proportion of people with secondary or higher education, which was rare at the time. To be precise, 20% of the adult male and 12% of the adult female population (for the subset of married population, see Table 1) had achieved a level of education higher than primary by 1897, which was approximately six times higher than in Estonia as a whole (Eesti Statistika Keskbüroo 1924, p. 46). Very few women had the opportunity to gain a tertiary education, since they were not admitted to the local university and had to go to St. Petersburg or Germany instead. The university, which was a major employer in Tartu (Leppik 2006), and other educational, medical and cultural institutions provided employment for the people with a secondary or tertiary education.

During the last decades of its existence the Tsarist Empire started to curtail the autonomy of the Baltic provinces and the power of the Baltic Germans (Thaden 1981). The main wave of Russification occurred between the mid-1880s and the mid-1890s, i.e. right before the 1897 census. It focused both on the legal-administrative domain as well as on the cultural-linguistic-religious domain. The central government widened its areas of competence and this brought about the increase of the number of state officials. Since at the same time the importance of the Russian language greatly grew in conducting public affairs and that of the German language fell (Kiverik 2010), these increasing numbers were made up to great extent by Russian immigrants, while the number and proportion of Baltic German officials declined (Raun 1995, pp. 92–93).

The blueprint for Russification was the senatorial inspection carried out by the then Senator and future imperial Minister of Justice Nikolai Manassein in 1882. In his report Manassein paid special attention to Tartu and its university, which he saw as the focal point of Baltic German particularism (Thaden 1981, pp. 58–59). In 1894 the name of the town and its university was changed from German Dorpat to Russian Yuryev and Russian became the main language of instruction in its university. This significantly lowered the proportion of

German academics and students and by the end of the century the share of German students had fallen below 40% (Tamul 2010). The Russian student became a new feature of the town (Leppik 2006, p. 92). Secondary schools were to a varying degree Russified a few years earlier and this also affected the ethnic makeup of its teachers and students (Kiverik 2010, pp. 42–49). The Jewish population grew as earlier restrictions on Jewish settlement were weakened from the 1860s onwards and more students came to study in Tartu (Jokton 1992, pp. 8–14).

Between the 1867 and 1897 censuses, the population of Tartu doubled as a result of the influx of Estonian peasant-origin population. This inflow of people changed the ethnic structure of the population: and between these two years the proportion of Estonians rose from 46% to 71% and the proportion of the Baltic Germans fell from 42% to 17% (Körber 1902, pp. 40–43). With the increase in their numerical strength, the Estonians also grew in educational, economic and political strength. The earlier trend that successful Estonians became Germanised ended and, in many cases, actually reversed (Jansen 2007, pp. 376–386; Haltzel 1981, p. 150). An increasing Estonian intellectual and entrepreneurial stratum became the backbone of the Estonian national movement and, due to its educational and cultural institutions, Tartu became its centre at the end of the century (Raun 2001, p. 75).

These developments can be seen in the age structure of Tartu population shown in Figures 1 and 2, providing numbers by ethnic and origin groups respectively. To indicate how the different family, fertility and migration patterns influence the marriage market both of the figures also make a distinction between marital statuses. The role of Tartu as an educational centre shows in both figures as the ages (especially for males) that attend secondary and tertiary institutions stand out from the population pyramids for all the ethnic groups (more so for the smaller Russian and Jewish communities, or those born abroad). Based on the pyramids, we assume that many students coming to Tartu remained single

during their studies. This can be explained by high cost of education but also by the lack of culturally similar mates.

(FIGURE 1 about here)

The student age group is a lot less evident for Estonians and those born in Estonia, who mostly moved to Tartu to work in the low-wage sector. As seen also in the population pyramids of Estonians and those born in Estonia, the influx of people had begun to slow down and the age groups in their thirties stand out more than the younger ones. This is also supported by population counts. During the thirty years before 1897 the population of Tartu had grown from 20494 to 40521. In the following decades the growth was modest and by 1919 the population size of the town was 45812 (Berendsen and Maiste, 2005, pp. 118–119).

The pyramid for the Germans in Figure 1 is much narrower at the bottom of the age structure. This is partly due to lower marital fertility, but even a bigger factor is the share of never-married, which for the German women in their forties was an astounding 31.3% (Estonians 16.6%). The majority of these never married German women came from noble and merchant background who lived in the wealthier areas of Tartu, but whose families probably had too little capital for marriage or who did not find “worthy” suiters. Compared to the Germans, the pyramids of Russians and Jews (who primarily originated from Polish and Lithuanian territories) is wider in the bottom, since they were not part of the European marriage pattern and experienced a later fertility transition (Coale and Watkins, 1986). Only a small share of Russians and no Jews remained unmarried by their forties.

(FIGURE 2 about here)

Research questions

Our question is how educational heterogamy, as a potential avenue of social mobility, was associated with marrying outside own cultural group. This question is analogous to the problem of age heterogamy, which says that brides were marrying outside their own age group because older men were wealthier.

To bring an example, less educated local women could marry a more educated foreign origin men, thus making a compromise on cultural similarity but gaining on the income potential of the husband. Moreover, such heterogamous union could be desirable for both partners (Kalmijn 2010; Merton 1941). As an example of such ‘exchange’ in the modern times, it has been found that highly educated immigrants may be interested in marrying low educated but locally established partners (Schwartz, Zeng, and Xie 2016). In the 19th century Tartu, even if we exclude foreign-born migrants, there was a lot of room for social and cultural intermarriage. For instance, the Baltic German women with a noble background and weakening family finances could have married local Estonian men who had made gains in education but lacked in social status.

Constructing hypotheses for our analysis, a basic assumption is that in an occupationally diverse urban environment, where the university and local schools were one of the largest employers in the town, individual’s education was clearly a positive asset. More education could be used to acquire economic benefits through higher paid jobs or by having a more respected position in the society. Thus, on the marriage market, a highly educated person was more attractive as a potential spouse than a person with less education, *ceteris paribus*. We also need to consider that higher social status and wealth facilitated gaining more education, because parents were in a better position to invest in their children. For this reason, on the marriage market the potential partner’s low education could be associated with a financially poor family background.

Our hypotheses cover three characteristics of the couple which we expect to predict educational heterogamy. First, we expect that the potential partner's education is one reason for individuals to marry outside own ethnic group. If this is so, educational heterogamy and ethnic heterogamy are positively correlated, thus we formulate:

Hypothesis 1: educational heterogamy is more likely if the husband and the wife are from different ethnic groups.

The second hypothesis is similar to the first, but instead of ethnicity it pertains to origin. Origin, indicated by a rough measure of place of birth, adds a dimension that ethnicity may not always cover. For instance, town-born individuals may be less interested in marrying rural-born people, despite their similar ethnic background. But, as with ethnic differences, educational level of the partner can be a motivation to form such a union:

Hypothesis 2: educational heterogamy is more likely if the husband and the wife have different migratory backgrounds.

Our third hypothesis is about the age difference. We expect that women were attracted to more educated men. Men, however, were interested in women who were relatively young as youth is generally associated with better chances in reproduction and, therefore, counts as an asset. Because of this, we expect a positive correlation between educational heterogamy and the husband-wife age difference.

Hypothesis 3: age difference between the spouses (the man's age minus the woman's age) is positively associated with the probability that the marriage is educationally heterogamous.

Although the reasoning behind our hypotheses may suggest certain causality, for instance that ethnically heterogamous unions were formed because of the intention to marry up in terms of education, we certainly are not able to infer causal relations from our data. Therefore, it is not reasonable to specify our hypotheses in a causal way. We can only infer and discuss associations.

3. Data and methods

We make use of data from the first imperial census of 1897 (Berendsen and Maiste 1999), including all married individuals in Tartu at the time of the enumeration. The analysis of educational heterogamy draws information from both partner's characteristics.

To establish the type of educational pairing, we used the educational level variable that had been derived from the school type (Berendsen and Maiste 1999). The school system at the time included a number of different primary and secondary education facilities that were not strictly comparable to each other. To accommodate this diversity, the educational level variable distinguishes two levels of primary education. The lower level of primary education was completed in three years (we also include in this category those who were home-schooled since the length of schooling cannot be determined for such cases). The higher level of primary education added further 1-2 years on top of that. Secondary education includes attendance in gymnasium or equivalent schools. Tertiary education means having a university degree. As a result, the level of education has four categories: lower primary, higher primary, secondary, and tertiary. Our binary dependent variable is derived from the

spouses' educational level and takes value 0 if the husband's education is the same as the wife's or 1 if they are different.

There are three main predictor variables – heterogamy by origin (place of birth), ethnic heterogamy, and age difference. The age difference variable is a continuous measure that subtracts the wife's age from the husband's age. Origin heterogamy is a binary indicator which takes value 0 if the spouses share the same broad category of birth place (born in Tartu, domestic migrant, or international migrant) and 1 if they are from different categories. To consider ethnic background, two types of basic information were available – mother tongue and religious denomination. Yet, for a large part of the population, including one of the characteristics makes the other one redundant, e.g. German and Estonian speakers tended to be mostly Lutheran, Russian speakers tended to be Orthodox, etc. We collapsed larger ethnic groups based on language, the Jews remained a separate group based on religion, and a small number of Catholics were grouped together with people of other, unidentified ethnic descent. This resulted in a five-category ethnicity variable: Estonians, Germans, Russians, Jews, and 'other'. The binary ethnic heterogamy variable indicates that the spouses do not belong in the same category. In addition to the two heterogamy dummy variables, in the models we include the origin of the wife and her ethnic background variables as defined above. In this way, we control for the differences in educational heterogamy levels between various ethnic and origin groups.

At the time, one of the most important markers of status was occupation. In most historical studies of status attainment and heterogamy, occupation is the default variable of interest. Unfortunately, in the case of Tartu 1897 census, for over 50% of women aged 16 and more, occupation is not recorded in the census (for men, 18%). Considering only married individuals, over 80% of women lack information on occupation whereas among men the percentage is less than five. As a result, both partners' occupation is available only for 16.6%

of the couples included in our analysis. Since it is difficult to determine whether married women's occupation is missing at random or not, women's occupational information could be very selective. For that reason, we are not able to address the question of occupational heterogamy in this study. The information on the husband's occupation, however, is used in an extended model to control for his social standing. His occupation is collapsed into five categories by combining the following broad groups: unskilled manual workers, skilled manual workers, lower non-manual workers, managers, and professionals (ILO 1990).

The second additional control variable to account for the husband's status is the social estate. As it was implemented in the census, it was a symbiosis of the local medieval notion of estate (clergy, nobility, urban citizens, peasantry) and the imperial table of ranks (Leppik, 2006). There were different categories of nobility, which we collapse into one for analysis. The category of the *literati* was made up of the educated professionals, which is not a traditional part of the estate system, but a 19th century addition. Notably, there was no category of workers, which means that the population of Tartu was at the time mostly made up of peasants (actually meaning peasant-origin), while the traditional urban upper and middle classes, the citizens (*Bürgers*) comprised only a fifth of the population (distributions among the married population are shown in Table 1).

Due to the educational expansion at the time, one of our expectations is that educational heterogamy is more likely in younger birth cohorts. For this reason, we control for the birth cohort of the wife. This variable indicates the decade in which she was born, ranging from the 1820s to 1870s.

Size of the original census data is 40565 individuals, including children and elderly. We analyse married people who were at least 15 years old at the time of the census. In order to consider educational pairing of the couple, individuals lacking information on the level of education (n=1730) had to be excluded. As a result, the final study sample consists of 5283

couples (see Table 1). In models that control for the husband's occupation, the sample size is further reduced to 4983 as for some men the relevant information is missing.

To test our hypotheses, we apply logistic regression modelling with stepwise addition of variables. First, we present bivariate models that each include only one of the three main predictor variables. In the second step, all three predictors are included simultaneously and the wife-specific control variables (her origin, ethnic group, and birth cohort) added. In the third step, we add husband-specific control variables (his occupation and social estate). We also fit both of these multivariate models separately for older (the wife born before 1860) and younger birth cohorts. In the final step of analysis, interaction effects between heterogamy dummies and the wife's background variables are estimated and reported graphically.

(Table 1 about here)

4. Results

Descriptive results

Table 1 shows the distributions of the main variables in the study sample. Most of the married population is at the lowest level of schooling. At the primary level, men are more likely to have upper primary education compared with women. At the post-primary level, women are almost all in the group of secondary education due to their limited access to universities (there are in total only 4 women with higher education in the sample). About 10% of men and 8.5% of women have secondary or higher education. It is known that at the time women with education beyond the primary level had a lower likelihood of family formation (see for example van Bavel et al. 2018), but these numbers show relatively similar proportions of married men and women in the post-primary group. Large majority, 81% of the sample is educationally homogamous, about 15% are in a traditional heterogamous union

in which the man is more educated, and less than 4% are those in which the wife has more education than the husband.

As shown in Table 1, most of the town dwellers were Estonian but born outside of Tartu. The proportion of men who had migrated from abroad was slightly higher than for women, and a larger proportion of women had been born in the town compared with men. In terms of social estate, most of the married town population had a peasant background and the second largest group were citizens. About two thirds of the married male population were skilled and unskilled workers, managers being the third largest occupation group. Women, if their occupation was registered, were most likely to be unskilled manual workers.

To illustrate how partnership status varies by age, we plot the percentage of married in the total town population (Figure 3). The married population is subdivided into educationally homogamous and heterogamous groups. For comparison, also the percentage of non-married population is shown. At younger ages, the proportion of singles is high for both men and women, reaching well over 50% for those aged 25–29. After age 40–44, the proportion of non-married males drops below 25% and does not change much at older ages. The proportion of non-married women declines until age 35–39 and increases again at older ages. Among the married population, educationally homogamous partnerships are dominant in all age groups, followed by marriages in which the man is more educated than the wife.

(Figure 3 about here)

Regression results

We present our regression tables in three steps. First, one unadjusted model using each main predictor separately. Second, adjusted models that include all main predictors and control for the wife's characteristics, separately for the total sample and different cohorts. Third, adjusted models that add the husband's status variables. In all regression models, the dependent variable is the binary indicator of heterogamy that takes value 1 if the husband and the wife have different levels of education. We comment first on the results of the main predictor variables in all fitted models and then examine control variables.

(Table 2 about here)

Unadjusted models are shown in Table 2. The odds of educational heterogamy are over four times higher in ethnically heterogamous unions compared with ethnically homogamous marriages. If the spouses come from different origin groups, it associates with three and a half times larger likelihood of educational heterogamy compared with marriages in which both share the same origin. Age difference is associated with higher odds of educational heterogamy. All three tested associations are highly statistically significant.

In Table 3, the three main predictor variables are included in one model that is adjusted for the wife's background characteristics. In the model that includes all birth cohorts, only origin heterogamy remains a statistically significant predictor of educational heterogamy: the couples that do not share the same origin group have about 60% higher chances of being in an educationally heterogamous union compared with couples who share origin. The other two heterogamy variables are not statistically significant. The results for the main predictor variables hold if we fit the model separately for cohorts born before 1860 and those born later. The contrast between origin heterogamy vs origin homogamy is smaller in

older cohorts (OR 1.422*) and larger in younger cohorts (OR 1.692***). Ethnic heterogamy makes only a small difference in older cohorts, but has a positive, almost statistically significant ($p=0.067$) association with educational heterogamy in younger cohorts.

(Table 3 about here)

Next, we add the husband's background variables to the model (Table 4). Origin heterogamy remains a positive and statistically significant predictor of educational heterogamy in the model that applies to the entire sample (OR 1.534***) and in the model that only includes younger birth cohorts (OR 1.694***). The variable is not statistically significant in the model that is applied to older cohorts. Somewhat surprisingly, age difference has a small negative effect on the odds of educational heterogamy in the model of older cohorts. Ethnic heterogamy is positively associated with educational heterogamy in all models but does not reach the level of statistical significance. In short, in these models we only find support for Hypothesis 2, which was about origin heterogamy.

Regarding the ethnic group control variable, Estonian women have lower odds of being in an educationally heterogamous union (all models in Table 3) compared with all other groups, except the Jewish. The models suggest that German and Russian wives were more often in educationally heterogamous marriages. This estimate for the wife's ethnic group holds also in models that control for the husband's characteristics, although the differences are smaller (all models in Table 4). Another change after adding the husband-specific control variables is that the Jewish wives have the lowest odds of educational heterogamy among all ethnic groups (M1 and M3 in Table 4).

(Table 4 about here)

The wife's origin is an important predictor in models that adjust only for the wife's characteristics. Those wives originating from Estonia but outside Tartu have lower odds of educational heterogamy than those born in Tartu (statistically significant difference in M1 and M3 in Table 3). Wives with an immigrant background, however, have relatively higher odds of educational heterogamy, compared with women born in Tartu (statistically significant in M1 in Table 3). When the husband-specific control variables are added, the difference between internal migrants and town-born women is statistically significant only in models including all cohorts and older cohorts (M1 and M2). We conclude that the gap in the odds of educational heterogamy between ethnic groups reduced over time and was becoming less relevant in younger birth cohorts.

With regard to differences between the wife's birth cohorts, there is a clear positive gradient over time (M1 in Table 3 and M1 in Table 4). Educational heterogamy is more common among younger cohorts. This is in accordance with our expectations about the influence of educational expansion.

To gain further insights into the associations between the spouses' background characteristics and educational heterogamy, we estimated two interaction models. First, we added interaction terms between the wife's ethnic group and the ethnic heterogamy dummy to model M1 in Table 4. Using the estimated model (full results shown in Table A1 in Appendix) we predicted the probability of educational heterogamy by interaction variables. The results, shown in Figure 4, suggest that among ethnically homogamous couples the Germans are most likely and the Jewish least likely to be in an educationally heterogamous union. However, if the husband's ethnic background is different from the wife's, the probability of educational heterogamy is almost at the same level for German, Russian, and Estonian women (the Jewish group includes no observations to estimate the interaction

effect).

We draw two important conclusions from this interaction model. First, we find support to Hypothesis 1: women of all ethnic groups have higher chances of educational heterogamy if they are married outside their own ethnic group (except the Jews, for which we do not have an estimate). Second, for some groups, like Estonians, marrying outside own group increases the probability of educational heterogamy more than for other ethnicities because of the low probability of heterogamy among ethnically homogamous unions. For others, especially Germans, the increase is smaller as ethnically homogamous unions have a relatively high probability of being heterogamous by education. This can be interpreted as a feature of the marriage market in Tartu – non-native women were more likely to find a differently educated partner within their own ethnic group while Estonian women had better chances at this by marrying outside own group.

(FIGURE 4 about here)

In the second interaction model (Table A2 in Appendix), also based on model M1 in Table 4, we interacted the wife's origin variable and the origin heterogamy indicator. Predicted values based on this model (Figure 5) suggest that origin heterogamy is positively associated with educational heterogamy for all women regardless of their origin. This confirms what was seen in Tables 3 and 4, corroborating support for Hypothesis 2. However, if the husband and the wife both are from the same origin group, then couples that were born abroad are slightly more likely to be educationally heterogamous than those born in Estonia outside Tartu. Couples from Tartu and from abroad who are homogamous by origin have overlapping confidence intervals in Figure 5, so we cannot say that they differ in the probability of educational heterogamy. If the couple is heterogeneous by origin, the wife's

birth place does not make much of a difference: for all three origin groups of the wife, the probability of educational heterogamy is estimated between 0.3 and 0.4, which is about double of that of couples who are homogamous by origin.

(FIGURE 5 about here)

5. Summary

We investigated educational heterogamy in the late 19th century Tartu, Estonia. Using data from the First imperial census of 1897, we were able to cover almost the entire married population of the town. Our main question was whether marriages between unequally educated partners were correlated with marrying outside own ethnic, origin or age group. The findings of our analysis suggest that educational heterogamy was more often observed among couples in which the wife and the husband were either from different ethnic groups or had a different background regarding their place of birth (origin). Against our expectation, however, age difference between partners was not positively correlated with the odds of educational heterogamy.

The finding that educational heterogamy in Tartu correlated with heterogamy by ethnicity or origin is not surprising. Earlier studies have found that migratory background of individuals associated with their partner's status origin (Zijdeman and Maas 2010; Roikonen and Häkkinen 2019). Other studies have pointed out that age heterogamy was more likely if one of the spouses was a migrant (van de Putte et al. 2009; Dribe and Stanfors 2017). It has also been found for rural populations that partner selection may involve 'exchange' of partner characteristics in different dimensions (Dribe and Lundh 2009). It is possible that our results reflect a similar pattern: heterogamy by ethnicity and origin correlate with educational heterogamy because intermarriage by ethnicity or origin was one way to form a union with a

more educated partner. We interpret our finding as a subtle evidence about the significance of education in this particular marriage market. This interpretation rests on the assumption that people generally tend to match with partners who are from the same cultural background and who have higher achieved characteristics like education (Kalmijn 1991b). Thus, an educationally and ethnically heterogamous union is a trade-off resulting from the choice to marry someone more educated at the expense of cultural dissimilarity, which speaks about the importance of education in partner selection.

Of course, there could have been other features that also correlated with marrying someone more educated. For example, since schooling was costly, higher level of education signaled a wealthier family background and we would be inclined to conclude that educationally upward marriages were motivated by parental wealth. Unfortunately, our data do not permit elaborating on the role of family wealth. In either case, however, the observed positive correlation between educational heterogamy and ethnic/origin group heterogamy could be explained by potential gains in status due to higher education of the spouse.

Main limitations of this study relate to the cross-sectional nature of our data. The spouses' characteristics that can be considered mostly apply to post-marriage period, thus it is difficult to estimate how important was education in the process of mate search and union formation. An additional limitation is the inability to distinguish first marriages from remarriages after widowhood. Considering that spouses often accumulated wealth in the first marriage, mate selection after widowhood may have been more influenced by the surviving partner's economic standing. Regarding comparability with studies that employ the intergenerational perspective of status attainment, the biggest drawback of our data is the lack of information on the social status of the spouses' parents. To overcome the cross-sectional nature of our analysis, other data sources such as vital statistics records may be considered to address these questions with a dynamic union formation analysis. Another potential

improvement over our approach is to extend the analysis to later periods and examine the growing importance of education on the marriage market.
