

# METRISABILITY OF THREE-DIMENSIONAL PATH GEOMETRIES

MACIEJ DUNAJSKI AND MICHAEL EASTWOOD

ABSTRACT. Given a projective structure on a three-dimensional manifold, we find explicit obstructions to the local existence of a Levi-Civita connection in the projective class. These obstructions are given by projectively invariant tensors algebraically constructed from the projective Weyl curvature. We show, by examples, that their vanishing is necessary but not sufficient for local metrisability.

## 1. INTRODUCTION

There are several inequivalent geometric structures that give rise to a preferred family of curves on a smooth  $n$ -manifold  $M$ . A *path geometry* on  $M$  is a locally defined family of unparametrised smooth curves (called *paths*), one through each point and in each direction. A path geometry is *projective* if its paths are the unparametrised geodesics of a torsion-free connection  $\nabla$  on  $TM$ . The corresponding projective structure  $(M, [\nabla])$  is then defined by the equivalence class of torsion-free connections sharing their unparametrised geodesics with  $\nabla$ . Finally a path geometry is *metrisable* if its paths are the unparametrised geodesics of a (pseudo-)Riemannian metric  $g$ . In this case the path geometry is, of course, also projective since the underlying projective structure is defined by the Levi-Civita connection of  $g$ . The converse does not hold: a general projective structure does not contain a Levi-Civita connection of any metric.

The characterisation of metrisable projective structures is a classical problem, which goes back to the work of Roger Liouville [19]. This problem has recently been solved if  $n = 2$ : in this case (assuming real-analyticity for sufficiency, as one must) necessary and sufficient conditions are given by the vanishing of a set of projective differential invariants [3], the simplest of which is of differential order five in the connection coefficients of a chosen  $\nabla \in [\nabla]$ . The case  $n = 2$  is special—the projective Weyl curvature vanishes on a surface. This is no longer the case if  $n = 3$ , where the first set of obstructions already arises at order one, and is algebraic in the projective Weyl tensor. In this paper we shall present some of these obstructions as explicit projectively invariant tensors constructed algebraically from the Weyl curvature.

As is often done in differential geometry, we shall adorn tensors with indices in order to denote the type of the tensor. Thus, we may denote a vector or vector field by  $X^a$  but  $\omega_a$  always denotes a co-vector or 1-form. The canonical pairing between vectors and co-vectors is denoted by repeating an index so that  $X^a\omega_a$  is the scalar that would often be written without indices as  $X \lrcorner \omega$ . For any tensor  $\psi_{abc}$ , we shall denote its skew part by  $\psi_{[abc]}$  and its symmetric part by  $\psi_{(abc)}$ . For example, if  $\omega_{ab}$  is a 2-form, then

$$\nabla_{[a}\omega_{bc]} \quad \text{and} \quad X^a\nabla_a\omega_{bc} - 2(\nabla_{[b}X^a)\omega_{c]a},$$

for any torsion-free connection  $\nabla_a$ , are the exterior derivative and the Lie derivative in the direction of the vector field  $X^a$ , respectively. Such formulae are not meant to imply any choice of local coördinates. More precisely, this is Penrose's *abstract index notation* [24].

Projective structures are reviewed at the start of Section 2. Here, suffice it to say that the primary invariant of a projective structure is the projective Weyl tensor  $W_{ab}{}^c{}_d$ , an irreducible part of the curvature of any connection in the projective class  $[\nabla]$  satisfying

$$W_{ab}{}^c{}_d = W_{[ab]}{}^c{}_d, \quad W_{[ab]}{}^c{}_d = 0, \quad W_{ab}{}^a{}_d = 0.$$

This article is concerned exclusively with the 3-dimensional case. To formulate one of our results define a traceless tensor  $V^{ab}{}_c = V^{(ab)}{}_c$  in terms of the projective Weyl curvature  $W_{ab}{}^c{}_d$  and an arbitrarily chosen non-degenerate section  $\epsilon^{abc}$  of  $\Lambda^3(TM)$  by

$$V^{ab}{}_c = \epsilon^{dea} W_{de}{}^b{}_c. \quad (1.1)$$

**Theorem 1.1.** *Let  $A, B, C, D, F, J, K, L$  be the symmetric tensors defined by*

$$\begin{aligned} A^{ab} &= \odot(V^{ap}{}_q V^{bq}{}_p), & B^{abc} &= \odot(V^{ap}{}_q V^{bq}{}_r V^{cr}{}_p), & C^{abc} &= \odot(V^{ab}{}_p V^{pq}{}_r V^{cr}{}_q), \\ D^{abcd} &= \odot(V^{ab}{}_p V^{pq}{}_r V^{cr}{}_s V^{ds}{}_q), & J^{abcdef} &= \odot(V^{ab}{}_p V^{cd}{}_q V^{pq}{}_r V^{er}{}_s V^{st}{}_u V^{fu}{}_t), \\ F^{abcd} &= \odot(V^{ab}{}_p V^{cd}{}_q V^{pr}{}_s V^{qs}{}_r), & K^{abcdef} &= \odot(V^{ab}{}_p V^{cd}{}_q V^{ep}{}_r V^{fq}{}_s V^{rt}{}_u V^{su}{}_t), \\ L^{abcdef} &= \odot(V^{ab}{}_p V^{cd}{}_q V^{pq}{}_r V^{rs}{}_t V^{et}{}_u V^{fu}{}_s), \end{aligned} \quad (1.2)$$

where  $\odot$  denotes symmetrisation over the non-contracted indices, and let

$$T = 24J + 12K - 24L - 24B \odot B - 24C \odot C + 40B \odot C - 24A \odot D + 6A \odot F. \quad (1.3)$$

In general, the tensor  $T^{abcdef}$  does not vanish. However, if  $\nabla$  is projectively equivalent to a Levi-Civita connection then  $T^{abcdef} \equiv 0$ .

**Theorem 1.2.** *With tensors  $A^{ab}, B^{abc}, C^{abc}, D^{abcd}, F^{abcd}, J^{abcdef}, K^{abcdef}, L^{abcdef}$  defined as in Theorem 1.1, the following*

$$\begin{aligned} C^{abc} - 2B^{abc}, & \quad F^{abcd} - 2D^{abcd}, & \quad J^{abcdef} - 2L^{abcdef}, \\ 3J^{abcdef} - 2C^{(abc}C^{def)}, & \quad J^{abcdef} - 4K^{abcdef} + 4A^{(ab}D^{cdef)} \end{aligned} \quad (1.4)$$

are generally non-zero but vanish if  $\nabla$  is projectively equivalent to a Levi-Civita connection.

In fact, since

$$\begin{aligned} T &= 12(J - 2L) - 3(J - 4K + 4A \odot D) + 5(3J - 2C \odot C) \\ &\quad + 2(C - 2B) \odot (6B - 7C) + 6A \odot (F - 2D), \end{aligned}$$

Theorem 1.2 implies Theorem 1.1. However, we shall see that the invariant  $T$  arises in a more fundamental way, already described in [3]. More specifically, one can construct from the Weyl curvature a homomorphism  $\Xi : \odot^2(TM) \rightarrow \odot^3(TM)$  that must have a non-trivial kernel in the metrisable case and  $T^{abcdef}$  is defined to be what amounts to the determinant of this homomorphism:  $T^{abcdef} X_a X_b X_c X_d X_e X_f$  is characterised as being the determinant of the composition

$$\odot^2(TM) \xrightarrow{\Xi} \odot^3(TM) \xrightarrow{X \lrcorner} \odot^2(TM)$$

for any 1-form  $X_a$ . The homomorphism  $\Xi$  is constructed by forming and prolonging the metrisability equation (e.g. [8]) and is the natural first step [22] in searching for a metric in a given projective class. We should point out that these constructions are carried out having arbitrarily chosen a non-zero section  $\epsilon^{abc}$  of the line bundle  $\Lambda^3(TM)$ . However, since a different section only changes the scale of the various obstruction tensors at each point, whether they vanish or not is unaffected. In the main body of this article we shall restore precision by introducing *projective weights*, in effect a mechanism for keeping track of the scale of  $\epsilon^{abc}$ .

Theorem 1.2 is established by a different route, which seemingly creates a proliferation of projectively invariant obstructions to metrisability. For example, if one considers tensors

such as  $T^{abcdef}$ , taking values in  $\odot^6(TM)$  and of degree 6 in the projective Weyl tensor, equivalently in the tensor  $V^{ab}_c$ , then one finds an 8-dimensional space of obstructions in the 11-dimensional space of projective invariants of this type. Indeed, there is already a quadratic obstruction as follows.

**Theorem 1.3.** *In order that a projective structure  $[\nabla]$  be metrisable, the invariant tensor*

$$Q_{ab}{}^c = \epsilon_{pq(a} V^{pr}{}_b) V^{qc}{}_r \quad (1.5)$$

*must vanish, whilst in general it does not.*

And if one prefers a scalar obstruction, then there is one of degree 3 as follows.

**Theorem 1.4.** *In order that a projective structure  $[\nabla]$  be metrisable, the invariant scalar*

$$S = \epsilon_{abc} V^{ap}{}_q V^{bq}{}_r V^{cr}{}_p$$

*must vanish, whilst in general it does not.*

Besides proving these theorems, we shall provide a systematic way of creating many more invariants. Nevertheless, we shall show by examples, in §2.3–2.4, that this proliferation of invariants is insufficient to characterise the metrisable projective structures. In Section 3 we shall reformulate the problem for path geometries in terms of systems of two second order ODE for the unparametrised paths.

We would like to thank Katharina Neusser for pointing out the projectively invariant pairing (2.13) as a useful device in understanding the metrisability equation and also for helpful discussions concerning the form of the tensor  $V^{ab}_c$  for the Egorov and Newtonian structures in §2.3–2.4.

Finally, as detailed in §2.3, we would like to thank Vladimir Matveev for drawing our attention to an alternative proof [17] of the non-metrisability of the Egorov structure and also for his pertinent comments concerning the possible values of the degree of mobility of Riemannian and Lorentzian metrics in 3 dimensions.

## 2. PROJECTIVE STRUCTURES AND METRISABILITY

Let  $M$  be a smooth manifold. Let us consider an equivalence class  $[\nabla]$  of torsion-free connections on  $TM$ , where to say that  $\nabla$  and  $\hat{\nabla}$  belong to  $[\nabla]$  is to say that there is a 1-form  $\Upsilon_a$  such that

$$\hat{\nabla}_a X^b = \nabla_a X^b + \Upsilon_a X^b + \delta_a{}^b \Upsilon_c X^c. \quad (2.6)$$

This is the condition for the geodesics sprays of  $\nabla$  and  $\hat{\nabla}$  on  $TM$  to have the same projection to  $\mathbb{P}(TM)$ . Therefore, it is exactly the condition that all connections in  $[\nabla]$  share the same unparametrised geodesics on  $M$ . In other words, the equivalence class  $[\nabla]$  operationally defines what is a projective structure.

The curvature of a given connection  $\nabla \in [\nabla]$  is defined by

$$[\nabla_a, \nabla_b] X^c = R_{ab}{}^c{}_d X^d,$$

and can be uniquely decomposed as

$$R_{ab}{}^c{}_d = W_{ab}{}^c{}_d + \delta_a{}^c P_{bd} - \delta_b{}^c P_{ad} + \beta_{ab} \delta_d{}^c \quad (2.7)$$

where  $\beta_{ab} = -2P_{[ab]}$  and  $W_{ab}{}^c{}_d$  is totally trace-free. Then  $P_{ab}$  is the *projective Schouten tensor* and  $W_{ab}{}^c{}_d$  is the *projective Weyl tensor*. If we change connection in the projective class using (2.6) then

$$\hat{P}_{ab} = P_{ab} - \nabla_a \Upsilon_b + \Upsilon_a \Upsilon_b, \quad \hat{\beta}_{ab} = \beta_{ab} + 2\nabla_{[a} \Upsilon_{b]},$$

whilst  $W_{ab}{}^c{}_d$  remains unchanged.

We now specialise to the case when  $M$  is 3-dimensional. Computing the effect of a change of connection (2.6) on a 3-form  $\eta_{abc}$ , we find that

$$\hat{\nabla}_a \eta_{bcd} = \nabla_a \eta_{bcd} - 3\Upsilon_a \eta_{bcd} - \Upsilon_b \eta_{acd} - \Upsilon_c \eta_{bad} - \Upsilon_d \eta_{bca} = \nabla_a \eta_{bcd} - 4\Upsilon_a \eta_{bcd} \quad (2.8)$$

and so if  $M$  is oriented (as we shall suppose henceforth) and  $\eta_{abc}$  is chosen to be everywhere non-vanishing (we say that  $\eta_{abc}$  is a *choice of scale*), then we may specify  $\Upsilon_a$  by requiring that  $\nabla_a \eta_{bcd} - 4\Upsilon_a \eta_{bcd} = 0$ , thus obtaining a unique connection  $\hat{\nabla}$  in the projective class such that  $\hat{\nabla}_a \eta_{bcd} = 0$ . We shall refer to the connections obtained in this way as *special*. From (2.7), we find that

$$[\nabla_a, \nabla_b] \eta_{cde} = -4\beta_{ab} \eta_{cde}$$

and conclude that  $\beta_{ab} = 0$  for special connections and hence that the Schouten tensor  $P_{ab}$  is symmetric. (If  $M$  is not oriented, then we define a choice of scale to be a nowhere-vanishing section of  $(\Lambda_M^3)^2$  instead, where  $\Lambda_M^3$  is the bundle of 3-forms on  $M$ .) For any  $w \in \mathbb{R}$ , it is convenient to denote by  $\mathcal{E}(w)$  the line bundle  $(\Lambda_M^3)^{-w/4}$ , invariantly defined as the bundle whose fibre at  $p \in M$  is the 1-dimensional vector space

$$\{\phi : \Lambda_+^3 T_p^* M \rightarrow \mathbb{R} \mid \phi(\lambda\omega) = \lambda^{w/4} \phi(\omega), \forall \lambda > 0\},$$

where  $\Lambda_+^3 T_p^* M$  denotes the 3-forms at  $p$  positive with respect to the orientation, and we shall refer to a section  $\rho$  of  $\mathcal{E}(w)$  as a *projective density of weight  $w$* . There are canonical isomorphisms  $\mathcal{E}(k) = \mathcal{E}(1)^{\otimes k}$  for  $k \in \mathbb{Z}$ . Also, by construction, there is an identification  $\mathcal{E}(-4) = \Lambda_M^3$ , which we shall write as  $\rho \mapsto \rho \epsilon_{abc}$  for  $\rho$  of projective weight  $-4$ . Equivalently, we have a canonical volume form  $\epsilon_{abc}$  of weight 4, that is to say a canonical section of  $\Lambda_M^3(4)$ , the tensor product  $\Lambda_M^3 \otimes \mathcal{E}(4)$ . Having done this, a scale may be alternatively specified as a nowhere-vanishing density  $\sigma$  of projective weight 1, so that  $\eta_{abc} = \sigma^{-4} \epsilon_{abc}$  is the corresponding volume form. This is the viewpoint we shall adopt henceforth. In summary, we are working with special connections specified by a choice of projective density  $\sigma$  of weight 1. Choosing a different scale, say  $\hat{\sigma} = \Omega^{-1} \sigma$  for some nowhere-vanishing function  $\Omega$ , induces a projective change of connection (2.6) where  $\Upsilon = \Omega^{-1} d\Omega$ . In the presence of a scale  $\sigma \in \Gamma(M, \mathcal{E}(1))$ , we may view a projective density  $\rho \in \Gamma(M, \mathcal{E}(w))$  as a smooth function, specifically  $f = \rho/\sigma^w$ , but if we change scale  $\sigma \mapsto \hat{\sigma} = \Omega^{-1} \sigma$ , then this function changes according to  $\hat{f} = \Omega^w f$ . Finally, for any scale  $\sigma \in \Gamma(M, \mathcal{E}(1))$ , the line bundles  $\mathcal{E}(w)$  inherit connections characterised by  $\nabla \sigma^w = 0$  and then, if  $\rho$  is a projective density of weight  $w$ , we see that

$$\hat{\nabla}_a \rho = \nabla_a \rho + w \Upsilon_a \rho$$

and note that this is consistent with (2.8) and the identification  $\Lambda_M^3 = \mathcal{E}(-4)$ . Otherwise said, the tautological 3-form  $\epsilon_{abc}$  of weight 4 is covariant constant ( $\nabla_a \epsilon_{bcd} = 0$ ) for any special connection on  $\Lambda_M^3(4)$ . We shall denote by  $\epsilon^{abc}$  the induced canonical section of the dual bundle  $\Lambda^3(TM)(-4)$  normalised so that

$$\epsilon_{abc} \epsilon^{def} = \delta_a^d \delta_b^e \delta_c^f + \delta_a^e \delta_b^f \delta_c^d + \delta_a^f \delta_b^d \delta_c^e - \delta_a^e \delta_b^d \delta_c^f - \delta_a^d \delta_b^f \delta_c^e - \delta_a^f \delta_b^e \delta_c^d,$$

equivalently that  $\epsilon^{abc} \epsilon_{abc} = 6$ .

For those who find this discussion arcane, we should admit that a low-tech alternative is to regard formulæ containing  $\epsilon^{abc}$  as defined using an arbitrarily chosen nowhere-vanishing section  $\epsilon^{abc}$  of  $\Lambda^3(TM)$  and that the projective weight simply keeps track of how these expressions change if  $\epsilon^{abc}$  is rescaled. Looking back at (1.1) now, we see that  $V^{ab}_c$  may be invariantly regarded as a tensor satisfying

$$V^{ab}_c = V^{(ab)}_c, \quad V^{ab}_a = 0, \quad \text{and of projective weight } -4.$$

Similarly, the scalar invariant  $S$  from Theorem 1.4 is a projective density of weight  $-8$ .

Even more arcane, yet correspondingly even more useful, is to record both the symmetries of a tensor and its projective weight by decorating a suitable Dynkin diagram in the style of [1]. An explanation sufficient for our purposes is as follows. We shall denote by  $\overset{k}{\times} \overset{l}{\bullet} \overset{m}{\bullet}$  the bundle of totally trace-free tensors

$$\begin{array}{c} \overbrace{S^{ab\dots c}}^{m \text{ contravariant indices}} \\ \underbrace{de\dots f}_{l \text{ covariant indices}} \end{array} \quad \text{of projective weight } k + 2l - m$$

and symmetric in its covariant and contravariant indices. These constitute a complete list of the irreducible bundles on an oriented projective 3-manifold as a parabolic geometry in the sense of [4]. It is also useful to introduce the *degree* of such a bundle as

$$\deg(\overset{k}{\times} \overset{l}{\bullet} \overset{m}{\bullet}) = -(3k + 2l + m)/4. \quad (2.9)$$

(It is the action of the *grading element* normalised as in [4].) The point about the degree is that it simply adds under tensor product, for example,

$$\Lambda_M^1 \otimes \Lambda_M^1 = \overset{-2}{\times} \overset{1}{\bullet} \overset{0}{\bullet} \otimes \overset{-2}{\times} \overset{1}{\bullet} \overset{0}{\bullet} = \overset{-4}{\times} \overset{2}{\bullet} \overset{0}{\bullet} \oplus \overset{-3}{\times} \overset{0}{\bullet} \overset{1}{\bullet} = \odot^2 T^*M \oplus \Lambda_M^2 \quad (2.10)$$

and changes sign when taking duals, for example,

$$\deg(TM) = \deg(\overset{1}{\times} \overset{0}{\bullet} \overset{1}{\bullet}) = -1 \quad \text{whilst} \quad \deg(\Lambda_M^1) = \deg(\overset{-2}{\times} \overset{1}{\bullet} \overset{0}{\bullet}) = 1.$$

Also notice that our previous discussion concerning projective weights and the tautologically defined tensors  $\epsilon_{abc}$  and  $\epsilon^{abc}$  is implicitly incorporated into this notation. For example, the identification  $\Lambda_M^2 = \overset{-3}{\times} \overset{0}{\bullet} \overset{1}{\bullet}$  in (2.10) is given by  $\omega_{ab} \mapsto \epsilon^{abc} \omega_{bc}$ . Fundamental for this article is (1.1), giving  $V^a{}_c \in \Gamma(M, \overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet})$  of projective weight  $-4$ . This irreducible tensor is every bit as good as the unweighted projectively invariant Weyl tensor  $W_{ab}{}^c{}_d$ , the inverse to (1.1) being given by  $W_{ab}{}^c{}_d = \frac{1}{2} \epsilon_{eab} V^{ec}$ .

**2.1. Metrisability.** As already remarked, a (pseudo-)Riemannian metric  $g$  on  $M$  gives rise to a projective structure  $[\nabla]$ , namely the one that contains the Levi-Civita connection of  $g$ . Hence we obtain a first order non-linear operator

$$J^1(\odot^2 \Lambda_M^1) \supset J^1(\odot_{\text{nd}}^2 \Lambda_M^1) \xrightarrow{\sigma^0} \text{Pr}(M), \quad (2.11)$$

which carries a metric to its associated projective structure, where

- $\odot^2 \Lambda_M^1$  is the vector bundle of symmetric covariant tensors,
- $\odot_{\text{nd}}^2 \Lambda_M^1$  is the subbundle of non-degenerate such tensors,
- $J^1(\odot^2 \Lambda_M^1)$  and  $J^1(\odot_{\text{nd}}^2 \Lambda_M^1)$  are their first jet bundles (e.g. [26]),
- $\text{Pr}(M)$  is the affine bundle of projective structures on  $M$ .

We note that, in the 3-dimensional case,

- $\odot^2 \Lambda_M^1$  is a vector bundle of rank 6,
- $J^1(\odot^2 \Lambda_M^1)$  is a vector bundle of rank 24,
- $J^1(\odot_{\text{nd}}^2 \Lambda_M^1)$  is a Zariski-open subbundle,
- $\text{Pr}(M)$  is modelled on  $\overset{-3}{\times} \overset{2}{\bullet} \overset{1}{\bullet}$ , which has rank 15.

Even taking into account that constant multiples of a given metric give rise to the same connection and hence the same projective structure, the dimensions indicate that  $\sigma^0$  should be surjective and it is easy to check, using local coördinates, that this is, indeed, the case. Differentiating (2.11), however, gives rise to its first prolongation

$$J^2(\odot_{\text{nd}}^2 \Lambda_M^1) \xrightarrow{\sigma^1} J^1(\text{Pr}(M))$$

where the left hand side is now a Zariski-open subbundle of a vector bundle of rank 60 whilst the right hand side is an affine bundle modelled on  $J^1(\overleftarrow{\times} \begin{smallmatrix} 3 \\ \bullet \\ 2 \\ \bullet \\ 1 \end{smallmatrix})$  a vector bundle also of rank 60. Taking scaling into account, it follows that  $\sigma^1$  cannot be surjective. In other words, already at first order in the projective structure, we expect to see obstructions to metrisability. Theorem 1.1 shows that, indeed, there are obstructions at this order which are algebraic in components of the projective Weyl curvature. There is no restriction on the value of this curvature as the following lemma shows.

**Lemma 2.1.** *Choose  $n \geq 3$  and let  $W_{ab}{}^c{}_d$  be any element of  $(\mathbb{R}^n)^* \otimes (\mathbb{R}^n)^* \otimes \mathbb{R}^n \otimes (\mathbb{R}^n)^*$  satisfying*

$$W_{ab}{}^c{}_d = W_{[ab]}{}^c{}_d, \quad W_{[ab}{}^c{}_d] = 0, \quad W_{ab}{}^a{}_d = 0. \quad (2.12)$$

*Let  $M$  be an  $n$ -dimensional manifold and let  $p \in M$  be an arbitrarily chosen point. Then there is a torsion-free connection on  $TM$  whose projective Weyl curvature at  $p$  is  $W_{ab}{}^c{}_d$ .*

*Proof.* The construction need only be local since connections can be patched together by a partition of unity. In local coördinates  $(x^1, x^2, \dots, x^n)$ , the connection

$$\nabla_b X^c = \frac{\partial X^c}{\partial x^b} + \frac{2}{3} x^a W_{a(b}{}^c{}_d) X^d$$

has projective Weyl curvature  $W_{ab}{}^c{}_d$  at the origin.  $\square$

In fact, the proof is also valid when  $n = 2$  but the statement is vacuous since only the zero tensor satisfies the symmetries (2.12). But for  $n = 3$  space of the tensors satisfying (2.12) is 15-dimensional. This is clear from the alternative encoding of the Weyl curvature as the tensor  $V^{ab}{}_c$  in (1.1) satisfying  $V^{ab}{}_c = V^{(ab)}{}_c$  and  $V^{ab}{}_a = 0$ . Alternatively, the dimension of any finite-dimensional irreducible tensor bundle can be computed from its highest weight and the Dynkin diagram notation established above is designed with this in mind. There are various algorithms and computer implementations thereof. For example

$$\text{rank} \left( \overleftarrow{\times} \begin{smallmatrix} k \\ \bullet \\ l \\ \bullet \\ m \end{smallmatrix} \right) = \text{dim}([1, m], A2)$$

where the right hand side of this equation is an instruction written in LiE [18]. We shall soon use LiE more seriously.

Henceforth, we shall use the terminology *metric* to mean (pseudo-)Riemannian metric. The signature plays no essential rôle in our considerations and can be discussed separately.

One can attack the metrisability problem directly, asking for a metric  $g_{ab}$  such that its Levi-Civita connection be projectively equivalent to a given connection. Although the resulting partial differential equations on  $g_{ab}$  are projectively invariant by construction, they are also non-linear. A surprising observation, essentially due to Liouville [19], is that there is a non-linear change of variables that turns this system into a linear one. For the convenience of the reader, we summarise the conclusions in 3 dimensions here and refer to [8, 21] for detail.

**Theorem 2.2.** *There is a projectively invariant linear differential operator*

$\odot^2(TM)(-2) = \overleftarrow{\times} \begin{smallmatrix} 0 \\ \bullet \\ 0 \\ \bullet \\ 2 \end{smallmatrix} \rightarrow \overleftarrow{\times} \begin{smallmatrix} -2 \\ \bullet \\ 1 \\ \bullet \\ 2 \end{smallmatrix}$  given by  $\sigma^{bc} \mapsto (\nabla_a \sigma^{bc})_\circ \equiv \nabla_a \sigma^{bc} - \frac{1}{2} \delta_a{}^b \nabla_d \sigma^{cd}$   
called the metrisability operator and a projectively invariant differential pairing

$$\overleftarrow{\times} \begin{smallmatrix} 0 \\ \bullet \\ 0 \\ \bullet \\ 2 \end{smallmatrix} \times \overleftarrow{\times} \begin{smallmatrix} 2 \\ \bullet \\ 0 \\ \bullet \\ 0 \end{smallmatrix} \rightarrow \overleftarrow{\times} \begin{smallmatrix} 1 \\ \bullet \\ 0 \\ \bullet \\ 1 \end{smallmatrix} \quad \text{given by} \quad (\sigma^{ab}, \tau) \mapsto \sigma^{ab} \nabla_b \tau - \frac{1}{2} \tau \nabla_b \sigma^{ab}. \quad (2.13)$$

If  $\sigma^{bc}$  is symmetric and of projective weight  $-2$ , i.e.  $\sigma^{bc} \in \Gamma(\overleftarrow{\times} \begin{smallmatrix} 0 \\ \bullet \\ 0 \\ \bullet \\ 2 \end{smallmatrix})$ , then

$$\det \sigma \equiv \frac{1}{6} \sigma^{ad} \sigma^{be} \sigma^{cf} \epsilon_{abc} \epsilon_{def}$$

is a projective density of weight 2, i.e.  $\det \sigma \in \Gamma(\overset{2}{\times} \overset{0}{\bullet} \overset{0}{\bullet})$ . If a tensor  $\sigma^{bc} \in \Gamma(\overset{0}{\times} \overset{0}{\bullet} \overset{2}{\bullet})$  satisfies the projectively invariant metrisability equation

$$(\nabla_a \sigma^{bc})_{\circ} = 0, \quad (2.14)$$

then the pairing with its determinant vanishes:

$$\sigma^{ab} \nabla_b (\det \sigma) - \frac{1}{2} (\det \sigma) \nabla_b \sigma^{ab} = 0. \quad (2.15)$$

Furthermore, wherever  $\det \sigma$  is non-zero, the weight zero tensor  $g^{ab} \equiv (\det \sigma) \sigma^{ab}$  defines a metric whose Levi-Civita connection lies in the given projective class. Finally, up to sign, all metrics in a given projective class arise in this manner.

*Proof.* As set forth in the statement of this theorem, these claims are straightforwardly verified from the definitions, the only further observation required being that (2.15) can be rewritten on  $\{\det \sigma \neq 0\}$  as  $\hat{\nabla}(g^{ab}) = 0$  where  $\hat{\nabla}_a$  is projectively equivalent to  $\nabla_a$  according to (2.6) if we take  $\Upsilon_a = -\frac{1}{4} g_{ab} (\det \sigma) \nabla_c \sigma^{bc}$ , where  $g_{ab}$  is the inverse to  $g^{ab}$ . (We have taken the opportunity here, following a suggestion of Katharina Neusser, to streamline the exposition in [8] by highlighting the rôle of (2.15).)  $\square$

An informal summary of Theorem 2.2 is that the metrisability of a given projective structure is controlled by the projectively invariant *metrisability equation* (2.14), there being a 2–1 correspondence between non-degenerate solutions of this equation and *positive* metrics in the projective class (note that  $\sigma^{ab}$  and  $-\sigma^{ab}$  give rise to the same metric, that these metrics have positive determinant (we call them *positive*), and that conversely if  $g^{ab}$  is such a metric, then

$$\sigma^{ab} \equiv (\det g)^{-1/4} g^{ab}$$

solves (2.14).)

**Theorem 2.3.** *If  $\sigma^{bc}$  solves the metrisability equation (2.14), then*

$$W_{ab}{}^c{}_e \sigma^{de} + W_{ab}{}^d{}_e \sigma^{ce} + \frac{2}{3} \delta_{[a}{}^c W_{b]e}{}^d{}_f \sigma^{ef} + \frac{2}{3} \delta_{[a}{}^d W_{b]e}{}^c{}_f \sigma^{ef} = 0. \quad (2.16)$$

*Proof.* If we write (2.14) as

$$\nabla_b \sigma^{cd} = \delta_b{}^c \mu^d + \delta_b{}^d \mu^c$$

for some field  $\mu^a$ , then

$$(\nabla_a \nabla_b - \nabla_b \nabla_a) \sigma^{cd} + 2\delta_{[a}{}^c \nabla_{b]} \mu^d + 2\delta_{[a}{}^d \nabla_{b]} \mu^c = 0 \quad (2.17)$$

but from (2.7) using, without loss of generality, a special connection

$$(\nabla_a \nabla_b - \nabla_b \nabla_a) \sigma^{cd} = W_{ab}{}^c{}_e \sigma^{de} + W_{ab}{}^d{}_e \sigma^{ce} + 2\delta_{[a}{}^c P_{b]e}{}^d{}_f \sigma^{ef} + 2\delta_{[a}{}^d P_{b]e}{}^c{}_f \sigma^{ef}$$

so it follows that

$$W_{ab}{}^c{}_e \sigma^{de} + W_{ab}{}^d{}_e \sigma^{ce} + 2\delta_{[a}{}^c \Psi_{b]}{}^d{}_e + 2\delta_{[a}{}^d \Psi_{b]}{}^c{}_e = 0 \quad (2.18)$$

where

$$\Psi_b{}^d{}_e = \nabla_b \mu^d + P_{be}{}^d{}_f \mu^f.$$

Tracing (2.18) over  $b{}^c$  yields

$$W_{ab}{}^d{}_e \sigma^{be} - 3\Psi_a{}^d{}_e + \delta_a{}^d \Psi_b{}^b{}_e = 0.$$

Finally, tracing this conclusion over  $a{}^d$  shows that  $\Psi_b{}^b{}_e = 0$  and substituting for  $\Psi_b{}^d{}_e$  back into (2.18) gives (2.16), as required.  $\square$

We remark that it is usual to establish (2.16) by firstly prolonging the metrisability operator, as is done in [8], to obtain a projectively invariant connection on an auxiliary vector bundle whose curvature is then computed and found to include the left hand side of (2.16). In fact, it is only necessary partially to prolong the operator before (2.16) emerges and this is exactly what is done in this proof. Notice that the vanishing of  $\Psi_b^b$ , observed at the end of the proof, implies that we can write  $\nabla_b \mu^d = \delta_b^d \rho - P_{be} \sigma^{de}$  for some smooth function  $\rho$  and, indeed, this would be the next stage in the general prolongation procedure advocated in [2]. This choice loses invariance, and in [8] (and also in [13, Example 3.4] in accordance with their general theory) it is found to be convenient to add some Weyl curvature to the right hand side

$$\nabla_b \mu^d = \delta_b^d \rho - P_{be} \sigma^{de} + \frac{1}{3} W_{be}^d{}_f \sigma^{ef}$$

eventually to obtain a projectively invariant connection. In this article we shall not pursue this prolongation procedure any further. It is already observed in [3] that (2.16) gives rise to non-trivial obstructions to metrisability. To express these obstructions in 3 dimensions, let us recall that  $W_{ab}{}^c{}_d = \frac{1}{2} \epsilon_{cab} V^{ec}{}_d$ , which enables us to rewrite (2.16) as

$$V^{(ab}{}_d \sigma^{c)d} = 0 \tag{2.19}$$

or, in other words, that

$$\Xi^{abc}{}_{de} \sigma^{de} = 0, \quad \text{where } \Xi^{abc}{}_{de} = V^{(ab}{}_d \delta_e)^c.$$

Taking projective weights into account, this defines an invariant homomorphism

$$\Xi: \odot^2(TM)(-2) = \overset{0}{\times} \overset{0}{\bullet} \overset{2}{\bullet} \longrightarrow \odot^3(TM)(-6) = \overset{-3}{\times} \overset{0}{\bullet} \overset{3}{\bullet}$$

and Theorem 2.3 may be recast as follows.

**Theorem 2.4.** *If  $\sigma^{bc}$  solves the metrisability equation (2.14), then  $\sigma^{bc}$  lies in the kernel of the endomorphism*

$$\Gamma(M, \odot^2(TM)(-2)) \ni \sigma^{de} \mapsto X_a \Xi^{abc}{}_{de} \sigma^{de} \in \Gamma(M, \odot^2(TM)(-2)) \tag{2.20}$$

for any projectively weighted 1-form  $X_a$  of weight 4.

*Proof of Theorem 1.1.* This is an almost immediate corollary of Theorem 2.4. As already observed in the introduction, as  $\odot^2 TM(-2)$  is a vector bundle of rank 6, the determinant of the endomorphism (2.20) has the form  $X_a X_b X_c X_d X_e X_f T^{abcdef}$  for some projectively invariant

$$T^{abcdef} \in \Gamma(M, \odot^6 TM(-24)) = \Gamma(M, \overset{-18}{\times} \overset{0}{\bullet} \overset{6}{\bullet}).$$

*A priori* this might always vanish but a suitable Weyl tensor  $W_{ab}{}^c{}_d$  is exhibited in [3, §8] with non-zero determinant (and this is realised by a projective structure in accordance with Lemma 2.1). It remains only to check that (1.3) gives a formula for  $T$  but this is easily accomplished with the aid of computer algebra.  $\square$

Since  $V^a{}_a = 0$ , it follows that  $\Xi^{abc}{}_{bc} = 0$  whence the endomorphism  $X_a \Xi^{abc}{}_{de}$  is traceless for any  $X_a$ . If we set  $\Xi_X^{bc}{}_{de} \equiv X_a \Xi^{abc}{}_{de}$ , the Cayley–Hamilton Theorem for traceless  $6 \times 6$  matrices now implies that the vanishing of  $T^{abcdef}$  is equivalent to the vanishing of

$$24 \operatorname{Tr}(\Xi_X^6) - 18 \operatorname{Tr}(\Xi_X^4) \operatorname{Tr}(\Xi_X^2) - 8 (\operatorname{Tr}(\Xi_X^3))^2 + 3 (\operatorname{Tr}(\Xi_X^2))^3,$$

which is a little easier to compute. Some further consequences of the vanishing of  $T^{abcdef}$  have been analysed in [5, 22]. Whilst a detailed analysis of the aforementioned prolonged system (as, for example, presented in [8, Theorem 3.1]) will surely lead to more obstructions, we do not pursue this here but, in the following section, opt for an alternative and more elementary approach. It leads to a plethora of invariant obstructions whose relation to the metrisability equation and its prolongation remains mysterious.

**2.2. An elementary construction of obstructions.** In three dimensions, the curvature of a metric connection is entirely captured by the Ricci curvature. Specifically,

$$R_{ab}{}^c{}_d = \delta_a{}^c R_{bd} - \delta_b{}^c R_{ad} - g_{ad} R_b{}^c + g_{bd} R_a{}^c - \frac{1}{2} R (\delta_a{}^c g_{bd} - \delta_b{}^c g_{ad}). \quad (2.21)$$

A metric connection is special and from (2.7) we see firstly that  $P_{ab} = \frac{1}{2} R_{ab}$  and hence that

$$W_{ab}{}^c{}_d = R_{ab}{}^c{}_d - \delta_a{}^c P_{bd} + \delta_b{}^c P_{ad} = R_{ab}{}^c{}_d - \frac{1}{2} \delta_a{}^c R_{bd} + \frac{1}{2} \delta_b{}^c R_{ad}.$$

From (2.21) we deduce that for a metric connection in three dimensions,

$$W_{ab}{}^c{}_d = \frac{1}{2} \delta_a{}^c R_{bd} - \frac{1}{2} \delta_b{}^c R_{ad} - g_{ad} R_b{}^c + g_{bd} R_a{}^c - \frac{1}{2} R \delta_a{}^c g_{bd} + \frac{1}{2} R \delta_b{}^c g_{ad}.$$

Therefore from its definition (1.1), we find that

$$V_{ab}{}^c{}_d = \epsilon^{dea} W_{de}{}^b{}_c = \epsilon^{bea} R_{ec} - 2\epsilon_c{}^{ea} R_e{}^b + \epsilon_c{}^{ba} R \quad (2.22)$$

**Lemma 2.5.** *For a metric connection  $V_{ab}{}^c{}_d = 2R^{d(a} \epsilon^{b)}$ .*

*Proof.* Though it might not appear so, the right hand of (2.22) is symmetric in  $ab$  as may be verified by computing

$$\epsilon_{dab} (\epsilon^{bea} R_{ec} - 2\epsilon_c{}^{ea} R_e{}^b + \epsilon_c{}^{ba} R) = 2\delta_d{}^e R_{ec} - 2(g_{bc} \delta_d{}^e - g_{dc} \delta_b{}^e) R_e{}^b - 2g_{dc} R = 0.$$

Symmetrising term-by-term in (2.22) gives the required formula.  $\square$

At first glance, it may seem that Lemma 2.5 cannot be useful in restricting the possible Weyl curvature of a metrisable projective structure because the metric is already involved in the formula for  $V_{ab}{}^c{}_d$  especially via the tensor  $\epsilon^{b}{}_{dc}$ . It turns out, however, that there are non-trivial projective covariants that necessarily vanish for  $V_{ab}{}^c{}_d$  of this special form no matter what metric and no matter what symmetric form  $R^{da}$  are chosen. The simplest example is  $Q_{ab}{}^c = \epsilon_{pq(a} V^{pr}{}_{b)} V^{qc}{}_r$  from Theorem 1.3.

*Proof of Theorem 1.3.* Firstly, let us establish that  $Q_{ab}{}^c$  does not always vanish. A general method that is almost instantly effective with a computer is simply to compute all the coefficients of  $Q_{ab}{}^c$  as polynomials in, for example, the 15 variables

$$\begin{aligned} &V^{11}{}_2, V^{11}{}_3, V^{21}{}_1, V^{21}{}_2, V^{21}{}_3, V^{22}{}_1, V^{22}{}_3, V^{31}{}_1, \\ &V^{31}{}_2, V^{31}{}_3, V^{32}{}_1, V^{32}{}_2, V^{32}{}_3, V^{33}{}_1, V^{33}{}_2, \end{aligned} \quad (2.23)$$

acting as coördinates on the space

$$\{V_{ab}{}^c \in \mathbb{R}^3 \otimes \mathbb{R}^3 \otimes (\mathbb{R}^3)^* \mid V_{ab}{}^c = V^{(ab)}{}_c, V^a{}_a = 0\},$$

any element of which can arise via (1.1) from the projective Weyl curvature of a suitable torsion-free connection in accordance with Lemma 2.1. Also, in this calculation, since there is only one totally skew 3-tensor up to scale, we may as well take

$$\epsilon_{123} = \epsilon_{231} = \epsilon_{312} = 1 \quad \text{and} \quad \epsilon_{213} = \epsilon_{132} = \epsilon_{321} = -1.$$

In this case, there is no real need for a computer to obtain, for example,

$$Q_{33}{}^3 = V^{11}{}_3 V^{32}{}_1 - V^{31}{}_1 V^{21}{}_3 - V^{31}{}_2 V^{22}{}_3 + V^{21}{}_3 V^{32}{}_2$$

and we are done. In fact, for low order invariants such as  $Q_{ab}{}^c$ , glancing ahead to our more systematic investigation starting with Proposition 2.7, non-vanishing can also be seen without calculation as follows. The decomposition (2.24) proves the existence of a non-zero covariant  $Q_{ab}{}^c = Q_{(ab)}{}^c$  and the only remaining issue is to find a formula for it. According to Weyl's first fundamental theorem of invariant theory [27] we are obliged to contract two copies of  $V_{ab}{}^c$  with (by counting the number of covariant and contravariant indices) one copy of  $\epsilon_{abc}$  and then take linear combinations. Bearing in mind the symmetries of  $V_{ab}{}^c$ , up

to scale the only possibility for  $Q_{ab}{}^c$  is (1.5). This is especially clear using *wiring diagrams* as in [24]:

$$\text{we know } \begin{array}{|c|} \hline \square \\ \hline \end{array} = 0 \quad \text{and} \quad \begin{array}{|c|} \hline \square \\ \hline \square \\ \hline \end{array} = 0 \quad \text{therefore} \quad Q_{ab}{}^c = \begin{array}{|c|} \hline \square \\ \hline \square \\ \hline \square \\ \hline \end{array}.$$

Now, we must show that  $Q_{ab}{}^c$  vanishes in the metrisable case. Well, if  $V^{ab}{}_c$  has the form given in Lemma 2.5, then we compute

$$\begin{aligned} \epsilon_{pqa} V^{pr}{}_b V^{qc}{}_r &= \epsilon_{pqa} (R^{dp} \epsilon^r{}_{db} + R^{dr} \epsilon^p{}_{db}) (R^{eq} \epsilon^c{}_{er} + R^{ec} \epsilon^q{}_{er}) \\ &= \epsilon_{pqa} \epsilon^r{}_{db} \epsilon^c{}_{er} R^{dp} R^{eq} + \epsilon_{pqa} \epsilon^r{}_{db} \epsilon^q{}_{er} R^{dp} R^{ec} \\ &\quad + \epsilon_{pqa} \epsilon^p{}_{db} \epsilon^c{}_{er} R^{dr} R^{eq} + \epsilon_{pqa} \epsilon^p{}_{db} \epsilon^q{}_{er} R^{dr} R^{ec} \\ &= \epsilon_{pqa} (\delta_d^c g_{be} - \delta_b^c g_{de}) R^{dp} R^{eq} + \epsilon_{pqa} (\delta_d^q g_{be} - \delta_b^q g_{de}) R^{dp} R^{ec} \\ &\quad + (g_{qd} g_{ab} - g_{ad} g_{qb}) \epsilon^c{}_{er} R^{dr} R^{eq} + (g_{qd} g_{ab} - g_{ad} g_{qb}) \epsilon^q{}_{er} R^{dr} R^{ec} \\ &= \epsilon_{pqa} R^{cp} R_b^q - \epsilon_{pqa} \delta_b^c R^{dp} R_d^q + \epsilon_{pqa} R^{qp} R_b^c - \epsilon_{pba} R^{dp} R_d^c \\ &\quad + g_{ab} \epsilon^c{}_{er} R_q{}^r R^{eq} - \epsilon^c{}_{er} R_a{}^r R_b^e + g_{ab} \epsilon_{der} R^{dr} R^{ec} - \epsilon_{ber} R_a{}^r R^{ec} \\ &= \epsilon_{pqa} R^{cp} R_b^q - \epsilon_{pba} R^{dp} R_d^c - \epsilon^c{}_{er} R_a{}^r R_b^e - \epsilon_{ber} R_a{}^r R^{ec} \\ &= \epsilon_{pqa} R^{cp} R_b^q + \epsilon_{abp} R^{dp} R_d^c + \epsilon^c{}_{re} R_a{}^r R_b^e - \epsilon_{bpq} R_a{}^q R^{cp}, \end{aligned}$$

which is evidently skew in  $ab$ , as required.  $\square$

Alternatively, we may compute in a preferred basis, the projective invariance ensuring that it does not matter what basis is chosen. In the Riemannian setting, for example, we may chose an orthonormal basis so that  $g_{ab}$  is represented by the identity matrix and in addition choose  $\epsilon_{abc}$  to be the associated volume form. We may also diagonalise  $R^{ab}$  and, optionally, remove its trace since  $g^{ab}$  does not contribute to  $V^{ab}{}_c = 2R^{d(a} \epsilon^{b)e}{}_{dc}$ . We leave the resulting verification to the reader. It is also straightforward to instruct a computer to work with these normalisations and this is our preferred method for analysing more complicated projective invariants. Finally, it is sufficient to work in the Riemannian setting:

**Proposition 2.6.** *Working at a point (so that the following statement is purely algebraic) suppose a projective covariant constructed from  $V^{ab}{}_c$  vanishes for all tensors of the form  $V^{ab}{}_c = 2R^{d(a} g^{b)e}{}_{dc}$  constructed from a fixed positive definite symmetric form  $g^{ab}$ , an associated volume form  $\epsilon_{abc}$ , and an arbitrary trace-free symmetric form  $R^{ab}$ . Then the same covariant also vanishes for any non-degenerate  $g^{ab}$ .*

*Proof.* Clear by complexification.  $\square$

In particular, when instructing a computer, it is sufficient to assume that  $g^{ab}$  and  $R^{ab}$  are simultaneously diagonalised: even though this might not be possible to arrange in the Lorentzian setting for example, as a statement of pure algebra it is densely true and this is good enough. In any case, we shall henceforth suppose that all metrics we encounter are positive definite.

Lemma 2.5 has a representation-theoretic interpretation as follows. Recall that on a 3-dimensional projective manifold, the tensor  $V^{ab}{}_c$  is a section of  $\overline{\times} \begin{array}{c} -4 \\ \bullet \\ \bullet \end{array} \begin{array}{c} 1 \\ \bullet \end{array} \begin{array}{c} 2 \\ \bullet \end{array}$ . This is an irreducible bundle but in the presence of a metric it decomposes according to the branching of the corresponding representation under

$$\mathrm{GL}_+(3, \mathbb{R}) \supset \mathrm{SO}(3).$$

Specifically,

$$\overline{\times} \begin{array}{c} -4 \\ \bullet \\ \bullet \end{array} \begin{array}{c} 1 \\ \bullet \end{array} \begin{array}{c} 2 \\ \bullet \end{array} = \begin{array}{c} 6 \\ \bullet \end{array} \oplus \begin{array}{c} 4 \\ \bullet \end{array} \oplus \begin{array}{c} 2 \\ \bullet \end{array}$$

where  $\bullet^{2k} = \odot_{\circ}^k TM$  and  $\circ$  denotes the trace-free tensors (and  $\overset{1}{\bullet}, \overset{3}{\bullet}, \dots$  denote spin bundles that need not concern us here). By Schur's Lemma, the homomorphisms  $\overset{4}{\bullet} \rightarrow \overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet}$  are unique up to scale so the embedding  $\overset{4}{\bullet} \hookrightarrow \overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet}$  may as well be realised concretely by Lemma 2.5. The other embeddings may as well be realised as

$$\Gamma(M, \odot_{\circ}^3 TM) \ni P^{abc} \mapsto P^{ab}_c \quad \text{and} \quad \Gamma(M, TM) \ni L^a \mapsto L^{(a}\delta^{b)}_c - 2g^{ab}L_c.$$

In order to construct potential obstructions by this approach, it is necessary firstly to construct projective covariants from the tensor  $V^{ab}_c$ . It is straightforward to compute the locations and dimensions of such covariants. Quadratic covariants, for example, are limited by the following result.

**Proposition 2.7.** *Up to scale, there are exactly 5 distinct quadratic covariants that may be constructed from  $V^{ab}_c$ , only one of which vanishes in the metrisable case.*

*Proof.* The usual theory of highest weights [11] allows us to decompose  $\odot^2(\overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet})$  into its irreducible subbundles and this is easily implemented with a computer. For example, the program LiE [18] decomposes the symmetric tensor power of any irreducible representation of any simple algebra. In our case

`sym_tensor(2, [1, 2], A2)`

returns

$$1X[0, 2] + 1X[1, 3] + 1X[2, 1] + 1X[2, 4] + 1X[4, 0],$$

which implies that

$$\odot^2(\overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet}) = \overset{-6}{\times} \overset{0}{\bullet} \overset{2}{\bullet} \oplus \overset{-7}{\times} \overset{1}{\bullet} \overset{3}{\bullet} \oplus \overset{-7}{\times} \overset{2}{\bullet} \overset{1}{\bullet} \oplus \overset{-8}{\times} \overset{2}{\bullet} \overset{4}{\bullet} \oplus \overset{-8}{\times} \overset{4}{\bullet} \overset{0}{\bullet}, \quad (2.24)$$

the numbers over the crossed nodes being controlled by the degree (2.9). This decomposition is exactly what we need to determine the location and multiplicity of quadratic covariants constructed from  $V^{ab}_c$ . The abstract theory does not give formulæ but, according to Weyl's first fundamental theorem of invariant theory [27], any such covariant can be expressed as a linear combination of contractions of  $V^{ab}_c$  itself with an appropriate multiplicity (in this case 2), together with the tautological form  $\epsilon_{abc}$  or its inverse  $\epsilon^{abc}$ . In our case, we find

$$\begin{aligned} A^{ab} &= V^{ap}_q V^{bq}_p = V^{p(a} V^{b)q}_{p} \in \Gamma(\overset{-6}{\times} \overset{0}{\bullet} \overset{2}{\bullet}), \\ N^{abc}_d &= 5V^{(ab}_p V^{c)p}_d - 2A^{(ab}\delta^{c)}_d \in \Gamma(\overset{-7}{\times} \overset{1}{\bullet} \overset{3}{\bullet}), \\ Q_{ab}{}^c &= \epsilon_{pq(a} V^{pr}_b) V^{qc}_r \in \Gamma(\overset{-6}{\times} \overset{2}{\bullet} \overset{1}{\bullet}), \\ Y^{abcd}_{ef} &= 105V^{(ab}_{(e} V^{cd)}_{f)} - 12N^{(abc}_{(e}\delta^{d)}_{f)} - 14A^{(ab}\delta_{(e}{}^c\delta_{f)}{}^d) \in \Gamma(\overset{-8}{\times} \overset{2}{\bullet} \overset{4}{\bullet}), \\ Z_{abcd} &= \epsilon_{pr(a} V^{pq}_b V^{rs}_c \epsilon_{d)qs} \in \Gamma(\overset{-8}{\times} \overset{4}{\bullet} \overset{0}{\bullet}), \end{aligned}$$

these formulæ being obtained by trial and error subject to the requirements only that the result be a non-vanishing tensor enjoying the specified symmetries (for then the formula is guaranteed by Schur's Lemma). It is then a matter of computation (best carried out with a computer) to check that only the invariant  $Q_{ab}{}^c$  vanishes when  $V^{ab}_c = 2R^{d(a}\epsilon^{b)}_{dc}$ .  $\square$

Unfortunately, we only know how to prove Proposition 2.7 by direct calculation. One might hope to prove it by looking at branching under  $SO(3) \subset SL_+(3, \mathbb{R})$  more carefully. LiE easily provides the branching. For example,

`branch([2, 4], A1, [[2], [2]], A2)`

returns

$$1X[0] + 2X[4] + 1X[6] + 2X[8] + 1X[10] + 1X[12],$$

which implies that

$$\overset{-8}{\times} \overset{2}{\bullet} \overset{4}{\bullet} = \overset{0}{\bullet} \oplus \overset{4}{\bullet} \oplus \overset{4}{\bullet} \oplus \overset{6}{\bullet} \oplus \overset{8}{\bullet} \oplus \overset{8}{\bullet} \oplus \overset{10}{\bullet} \oplus \overset{12}{\bullet}.$$

Similarly,

$$\begin{array}{l} \begin{array}{c} \begin{array}{c} \times \xrightarrow{-6} \bullet \xrightarrow{0} \bullet \xrightarrow{2} \bullet \\ \times \xrightarrow{-6} \bullet \xrightarrow{2} \bullet \xrightarrow{1} \bullet \end{array} \\ \begin{array}{c} \bullet \oplus \bullet \\ \bullet \oplus \bullet \oplus \bullet \end{array} \end{array} \\ \begin{array}{c} \begin{array}{c} \times \xrightarrow{-7} \bullet \xrightarrow{1} \bullet \xrightarrow{3} \bullet \\ \times \xrightarrow{-4} \bullet \xrightarrow{4} \bullet \xrightarrow{0} \bullet \end{array} \\ \begin{array}{c} \bullet \oplus \bullet \oplus \bullet \oplus \bullet \\ \bullet \oplus \bullet \oplus \bullet \oplus \bullet \end{array} \end{array} \end{array}$$

whereas invariants arising from  $V^{ab}{}_c = 2R^{d(a}\epsilon^{b)}{}_{dc}$  must lie in

$$\odot^2(\bullet) = \bullet \oplus \bullet \oplus \bullet.$$

At this point, however, a comparison leads nowhere.

Whilst we have no theoretical justification for why we might expect obstructions created in this way, the method of proof given above allows a systematic though computationally intensive method of finding many more as the following proofs show.

*Proof of Theorem 1.4.* In fact, noticing that

$$S = \epsilon_{abc} V^{ap}{}_q V^{bq}{}_r V^{cr}{}_p = V^{ap}{}_q \epsilon_{abc} V^{cr}{}_p V^{bq}{}_r = -V^{ab}{}_c Q_{ab}{}^c,$$

its vanishing in the metrisable case is immediate corollary of Theorem 1.3. A systematic approach to finding  $S$ , however, is to consider the decomposition

$$\begin{aligned} \odot^3(\times \xrightarrow{-4} \bullet \xrightarrow{1} \bullet \xrightarrow{2} \bullet) &= \begin{array}{c} \begin{array}{c} \times \xrightarrow{-8} \bullet \xrightarrow{0} \bullet \xrightarrow{0} \bullet \\ \times \xrightarrow{-9} \bullet \xrightarrow{0} \bullet \xrightarrow{3} \bullet \\ \times \xrightarrow{-9} \bullet \xrightarrow{0} \bullet \xrightarrow{3} \bullet \\ \times \xrightarrow{-10} \bullet \xrightarrow{0} \bullet \xrightarrow{6} \bullet \\ \times \xrightarrow{-9} \bullet \xrightarrow{1} \bullet \xrightarrow{1} \bullet \end{array} \\ \oplus \begin{array}{c} \times \xrightarrow{-10} \bullet \xrightarrow{1} \bullet \xrightarrow{4} \bullet \\ \times \xrightarrow{-10} \bullet \xrightarrow{1} \bullet \xrightarrow{4} \bullet \\ \times \xrightarrow{-10} \bullet \xrightarrow{2} \bullet \xrightarrow{2} \bullet \\ \times \xrightarrow{-10} \bullet \xrightarrow{2} \bullet \xrightarrow{2} \bullet \\ \times \xrightarrow{-11} \bullet \xrightarrow{2} \bullet \xrightarrow{5} \bullet \end{array} \\ \oplus \begin{array}{c} \times \xrightarrow{-10} \bullet \xrightarrow{3} \bullet \xrightarrow{0} \bullet \\ \times \xrightarrow{-10} \bullet \xrightarrow{3} \bullet \xrightarrow{0} \bullet \\ \times \xrightarrow{-11} \bullet \xrightarrow{3} \bullet \xrightarrow{3} \bullet \\ \times \xrightarrow{-11} \bullet \xrightarrow{3} \bullet \xrightarrow{3} \bullet \\ \times \xrightarrow{-12} \bullet \xrightarrow{3} \bullet \xrightarrow{6} \bullet \end{array} \\ \oplus \begin{array}{c} \times \xrightarrow{-11} \bullet \xrightarrow{4} \bullet \xrightarrow{1} \bullet \\ \times \xrightarrow{-12} \bullet \xrightarrow{5} \bullet \xrightarrow{2} \bullet \end{array} \end{array} \quad (2.25) \end{aligned}$$

immediately obtained from LiE, write each of them as a linear combination of contractions, and then test each of these potential obstructions by substituting  $V^{ab}{}_c = 2R^{d(a}\epsilon^{b)}{}_{dc}$ . This quickly leads to  $S$  as stated in Theorem 1.4. Finally, the veracity of our claimed formula for  $S$  may be instantly tested (with a computer) by simply calculating the result in our preferred variables (2.23), obtaining  $S = 6(V^{21}{}_1)^2 V^{31}{}_2 + 3V^{31}{}_1 V^{21}{}_1 V^{31}{}_3 + \dots$ , and observing that it is non-zero.  $\square$

This reasoning leads to many other cubic covariants. One immediate difference to the decomposition (2.24), however, is that some subbundles occur with multiplicity. That  $\times \xrightarrow{-9} \bullet \xrightarrow{0} \bullet \xrightarrow{3} \bullet$  occurs with multiplicity 2, for example, leads to the covariants

$$B^{abc} = \odot(V^{ap}{}_q V^{bq}{}_r V^{cr}{}_p) \quad \text{and} \quad C^{abc} = \odot(V^{ab}{}_p V^{pq}{}_r V^{cr}{}_q)$$

as stated in Theorem 1.1. Regarding the first conclusion of Theorem 1.2, it remains to check, by direct calculation, that  $B^{abc}$  and  $C^{abc}$  are linearly independent in general but that  $C^{abc} = 2B^{abc}$  when  $V^{ab}{}_c$  is of the form  $2R^{d(a}\epsilon^{b)}{}_{dc}$ . In fact, the obstruction  $C^{abc} - 2B^{abc}$  also arises from  $Q_{ab}{}^c$ . Specifically,

$$\begin{aligned} 2\epsilon^{pqa} Q_{pr}{}^b V^{cr}{}_q &= 2\epsilon^{pqa} \epsilon_{de(p} V^{ds}{}_r) V^{eb}{}_s V^{cr}{}_q \\ &= \epsilon^{pqa} \epsilon_{dep} V^{ds}{}_r V^{eb}{}_s V^{cr}{}_q + \epsilon^{pqa} \epsilon_{der} V^{ds}{}_p V^{eb}{}_s V^{cr}{}_q \\ &= (\delta_d^q \delta_e^a - \delta_d^a \delta_e^q) V^{ds}{}_r V^{eb}{}_s V^{cr}{}_q + \epsilon^{pqa} \epsilon_{der} V^{ds}{}_p V^{eb}{}_s V^{cr}{}_q \\ &= V^{qs}{}_r V^{ab}{}_s V^{cr}{}_q - V^{as}{}_r V^{qb}{}_s V^{cr}{}_q + (\delta_d^p \delta_e^q \delta_r^a + \dots) V^{ds}{}_p V^{eb}{}_s V^{cr}{}_q \\ &= 2V^{ab}{}_p V^{pq}{}_r V^{cr}{}_q - V^{ac}{}_p V^{pq}{}_r V^{br}{}_q - 2V^{ap}{}_q V^{cq}{}_r V^{br}{}_p \end{aligned}$$

and so

$$2\epsilon^{pqa} Q_{pr}{}^b V^{cr}{}_q = C^{abc} - 2B^{abc}.$$

*Proof of Theorem 1.2.* We have just shown that  $C^{abc} - 2B^{abc} = 0$  in the metric case, either by direct computation or as a consequence of the vanishing of the quadratic covariant  $Q_{ab}{}^c$

from Theorem 1.3. Generally, it is non-zero. The remaining claims in Theorem 1.2 may be straightforwardly checked by direct computation (with a computer).  $\square$

It is unclear whether all obstructions in Theorem 1.2 may be written in terms of  $Q_{ab}^c$ . More generally, it is straightforward to generate many more invariant obstructions all of which may yet arise from the basic obstruction  $Q_{ab}^c$ . We leave this question for a future investigation and content ourselves with the following complete determination of the sextic obstructions taking values in  $\overset{-18}{\times} \overset{0}{\bullet} \overset{6}{\bullet}$  (as does  $T^{abcddef}$  from Theorem 1.1).

**Theorem 2.8.** *There is an 11-dimensional space of covariants of  $V_c^{ab}$  of degree 6 taking values in  $\overset{-18}{\times} \overset{0}{\bullet} \overset{0}{\bullet}$ , an 8-dimensional subspace of which vanishes in the metrisable case.*

*Proof.* The first statement is that  $\overset{-18}{\times} \overset{0}{\bullet} \overset{6}{\bullet}$  occurs with multiplicity 11 in  $\odot^6(\overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet})$  and, since  $\deg(\overset{-18}{\times} \overset{0}{\bullet} \overset{6}{\bullet}) = 12 = 6 \times \deg(\overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet})$  from (2.9), it suffices to check that the multiplicity of  $\overset{0}{\bullet} \overset{6}{\bullet}$  in  $\odot^6(\overset{1}{\bullet} \overset{2}{\bullet})$  is 11. The LiE [18] command

`sym_tensor(6, [1, 2], A2) | [0, 6]`

confirms this (in less than one hundredth of a second). Finding a basis for this space is then a matter of trial and error. For this purpose, rather than using indices, it is easier to write covariants using *wiring diagrams* as was done in the 19<sup>th</sup> century [7] (see also [24]). Thus, the covariants  $A^{ab}$ ,  $B^{abc}$ , and  $C^{abc}$  from Theorem 1.1 are written as

Recall from (2.25) that  $\overset{-9}{\times} \overset{0}{\bullet} \overset{3}{\bullet}$  occurs with multiplicity 2 in  $\odot^3(\overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet})$  that  $B^{abc}$  and  $C^{abc}$  span the covariants of this type. At quartic level,

`sym_tensor(4, [1, 2], A2) | [0, 4]`

returns 4 and we already have  $A^{(ab}A^{cd)}$  so we are looking for 3 more linearly independent covariants. The following suffice.

Note that one might naïvely also expect to encounter the covariant

and in higher dimensions this would, indeed, be an independent covariant. In 3 dimensions, however, it turns out that this is  $\frac{1}{2}A^{(ab}A^{cd)}$ . In principle, such relations are covered by Weyl's second fundamental theorem of invariant theory [27], which says that they all arise by 'skewing over too many indices,' in this case 4 (the Cayley-Hamilton Theorem being a familiar example of such dimension-dependent relations). In practise, however, it is best to write down all potential covariants and allow a computer to sort out the relations.

For completeness, we now move on to quintic invariants. Since

$\text{sym\_tensor}(5, [1, 2], A2) | [0, 5]$

returns 5 we need 3 more invariants to complement  $A^{(ab}B^{cde)}$  and  $A^{(ab}C^{cde)}$ . It turns out that

$$G^{abcde} = \text{diagram}_1 \quad H^{abcde} = \text{diagram}_2 \quad I^{abcde} = \text{diagram}_3$$

will suffice (amongst the 7 possible quintic wiring diagrams beyond  $A^{(ab}B^{cde)}$  and  $A^{(ab}C^{cde)}$ ).

Finally we come to identify the sextic invariants and already we have

$$A^{(ab}A^{cd}A^{ef)}, \quad B^{(abc}B^{def)}, \quad C^{(abc}C^{def)}, \\ B^{(abc}C^{def)}, \quad A^{(ab}D^{cdef)}, \quad A^{(ab}E^{cdef)}, \quad A^{(ab}F^{cdef)}.$$

It remains to find 4 more and it turns out that

$$J^{abcde} = \text{diagram}_4 \quad K^{abcde} = \text{diagram}_5 \quad L^{abcde} = \text{diagram}_6 \quad M^{abcde} = \text{diagram}_7$$

will suffice. It is then a matter of computation (with a computer) to check that, in addition to the 5 obstructions listed in Theorem 1.2, there are two more, namely

$$E^{abcd} - F^{abcd} \quad \text{and} \quad J^{abcdef} - M^{abcdef},$$

but that there are no more relations amongst  $A, B, C, D, E, F, J, K, L$ . Therefore, amongst the 11-dimensional space of covariants of degree 6, the subspace comprising those that vanish in the metrisable case is 8-dimensional and is spanned by

$$J - M, \quad J - 2L, \quad 3J - 2C \odot C, \quad J - 4K + 4A \odot D, \\ A \odot E - A \odot F, \quad A \odot F - 2A \odot D, \quad B \odot C - 2B \odot B, \quad C \odot C - 2B \odot C,$$

for example. □

**2.3. Egorov's projective structure.** A *projective symmetry* is a vector field whose local flow maps unparametrised geodesics to unparametrised geodesics. Such symmetries form a Lie algebra  $\mathfrak{g}$  under Lie bracket and, for connected 3-dimensional projective structures, we have  $\dim \mathfrak{g} \leq 15$  with equality if and only if  $\mathfrak{g} = \mathfrak{sl}(4, \mathbb{R})$  in which case the structure is projectively flat, equivalently  $V^{ab}_c \equiv 0$ .

The submaximal dimension for simply-connected 3-dimensional projective structures is 8. The corresponding projective structure was given by Egorov [9] and can be represented in local coordinates  $(x^1, x^2, x^3)$  as

$$\nabla_2 X^1 = \partial_2 X^1 + x^2 X^3, \quad \nabla_3 X^1 = \partial_3 X^1 + x^2 X^2, \quad \text{else} \quad \nabla_a X^c = \partial_a X^c, \quad (2.26)$$

where  $\partial_a \equiv \partial/\partial x^a$ . For this connection, the only non-zero components of curvature are

$$R_{23}{}^1{}_2 = -1 \quad R_{32}{}^1{}_2 = 1$$

so  $R_{ab}{}^c{}_d$  is already trace-free. Therefore  $W_{ab}{}^c{}_d = R_{ab}{}^c{}_d$ . Hence

$$V^{11}{}_2 = -2 \quad \text{with all other components zero.} \quad (2.27)$$

Immediately (2.19) implies  $\sigma^{12} = \sigma^{22} = \sigma^{23} = 0$  and then we can solve (2.14) explicitly:

$$\sigma^{ab} = \begin{bmatrix} A - B(x^2)^2 + C(x^2)^4 & 0 & B - 2C(x^2)^2 \\ 0 & 0 & 0 \\ B - 2C(x^2)^2 & 0 & 4C \end{bmatrix} \quad (2.28)$$

for arbitrary constants  $A, B, C$ . Since all solutions are degenerate, we have shown:

**Proposition 2.9.** *The Egorov projective structure is not metrisable.*

*Another Proof.* As soon as the dimension of the solution space to (2.14) reaches 3, the projective structure cannot be metrisable unless it is projectively flat (it is easy to check that (2.28) solves (2.14) and that the projective Weyl curvature is non-vanishing without knowing that (2.28) is the general solution). In general, the *degree of mobility* of a metric is the dimension of the solution space of (2.14) for the associated projective structure and in 3 dimensions it can only be 1, 2, or 10 (as shown in [16] in the Riemannian case and [14] in the Lorentzian case (see [15, 25] in the Riemannian setting and [10] in the Lorentzian setting for a detailed analysis concerning possible values of the degree of mobility in all dimensions (in [10], a detailed analysis is conducted under the assumption that there are at least two metrics in the projective class whose corresponding Levi-Civita connections are different but if this is not the case, then this is a sufficient imposition on the projective Weyl curvature that it must vanish))). Alternatively, Kruglikov and Matveev [17] consider the dimension of the space of local projective symmetries to conclude that the Egorov structure is not metrisable. Specifically, in 3 dimensions they show that the dimension of this space is bounded by 5 if there is a Riemannian metric inducing the projective structure and 6 if there is a Lorentzian metric inducing the projective structure (whereas, as noted above, the local projective symmetries are 8-dimensional for the Egorov structure).  $\square$

*Yet Another Proof.* We consider the projective Weyl curvature of the Egorov structure in comparison with Lemma 2.5. To make the comparison, let us use the metric to lower indices:

$$V_{abc} = 2R^d{}_{(a}\epsilon_{b)dc}, \quad \text{which implies that } V_{(abc)} = 0. \quad (2.29)$$

As a consequence of (2.27), however,  $V^{ab}{}_c$  is simple, i.e. there are non-zero  $X^a$  and  $Y_a$  such that  $V^{ab}{}_c = X^a X^b Y_c$ . Therefore we have  $V_{(abc)} = X_{(a} X_b Y_{c)} \neq 0$ , in conflict with (2.29).  $\square$

Thus, we have yet another proof, this one just from the Weyl curvature, that the Egorov projective structure is not metrisable. On the other hand, for  $V^{ab}{}_c$  as in (2.27), projecting  $V \odot V \odot \cdots \odot V$  into any component of

$$\odot^d \left( \overset{-4}{\times} \overset{1}{\bullet} \overset{2}{\bullet} \right) = \overset{-4d}{\times} \overset{d}{\bullet} \overset{2d}{\bullet} \oplus \cdots$$

other than the first evidently gives zero. Thus, we see that the Weyl curvature is sufficiently special that the structure cannot be metrisable but that this situation cannot be detected by the vanishing of any projective covariant.

Finally, we remark that, although the Weyl tensor  $V^{ab}{}_c$  for the Egorov structure does not have the form required by Lemma 2.5, it can still be written as

$$V^{ab}{}_c = 2R^{d(a} g^{b)e} \epsilon_{edc}, \quad \text{where } R^{ab} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \quad \text{and } g^{ab} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

which is of the required form save for  $g^{ab}$  being degenerate.

**2.4. Newtonian projective structures.** In this section we construct some more non-metrisable projective structures notwithstanding that, again, all our obstructions vanish. Indeed, any obstruction that depends continuously on the projective structure will vanish for these *Newtonian* projective structures because they are created as limits of metrisable structures as follows. In local coördinates  $(x^1, x^2, x^3)$ , consider the metric

$$\epsilon((dx^1)^2 + (dx^2)^2) + \exp(\epsilon f(x^1, x^2))(dx^3)^2$$

where  $\epsilon \neq 0$  is constant and  $f(x^1, x^2)$  is an arbitrary smooth function. The corresponding projective structures are metrisable by definition but if we let  $\epsilon \rightarrow 0$ , then these metric connections have a perfectly good limit, namely

$$\nabla_3 X^1 = \partial_3 X^1 - \frac{1}{2}(\partial_1 f)X^3, \quad \nabla_3 X^2 = \partial_3 X^2 - \frac{1}{2}(\partial_2 f)X^3, \quad \text{else} \quad \nabla_a X^c = \partial_a X^c, \quad (2.30)$$

(whose geodesic equations are Newton's equations for a particle in the  $(x^1, x^2)$ -plane moving under the influence of the potential  $f(x^1, x^2)$  with  $x^3 =$  'time') whereas

**Proposition 2.10.** *Unless projectively flat, the Newtonian projective structures (2.30) are not metrisable.*

*Proof.* Firstly, we compute the curvature of (2.30)

$$\begin{aligned} R_{13}{}^1{}_3 &= -\frac{1}{2}(\partial_1)^2 f & R_{13}{}^2{}_3 &= -\frac{1}{2}\partial_1 \partial_2 f & R_{23}{}^1{}_3 &= -\frac{1}{2}\partial_1 \partial_2 f & R_{23}{}^2{}_3 &= -\frac{1}{2}(\partial_2)^2 f \\ R_{31}{}^1{}_3 &= \frac{1}{2}(\partial_1)^2 f & R_{31}{}^2{}_3 &= \frac{1}{2}\partial_1 \partial_2 f & R_{32}{}^1{}_3 &= \frac{1}{2}\partial_1 \partial_2 f & R_{32}{}^2{}_3 &= \frac{1}{2}(\partial_2)^2 f \end{aligned}$$

to discover that  $P_{33} = -\frac{1}{4}((\partial_1)^2 + (\partial_2)^2)f$  with all other components zero and hence that

$$V^ab{}_c = \epsilon^{dea} W_{de}{}^b{}_c = \epsilon^{dea} R_{de}{}^b{}_c - 2\epsilon^{bea} P_{ec}$$

is given by

$$V^ab{}_3 = \begin{bmatrix} -\partial_1 \partial_2 f & \frac{1}{2}((\partial_1)^2 - (\partial_2)^2)f & 0 \\ \frac{1}{2}((\partial_1)^2 - (\partial_2)^2)f & \partial_1 \partial_2 f & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (2.31)$$

with all other components zero. If  $f(x^1, x^2) = \alpha x^1 + \beta x^2 + \gamma$ , then  $V^ab{}_c$  vanishes and the structure is projectively flat. Otherwise the constraint (2.19) implies that  $\sigma^{c3} = 0$  for all  $c$ . Already, all solutions to (2.14) are degenerate so the structure is not metrisable. In fact, one can go on to check that

$$\sigma^{ab} = \begin{bmatrix} A & B & 0 \\ B & C & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

is the general solution of (2.14) for arbitrary constants  $A, B, C$ . As for the Egorov example, this 3-dimensional space of solutions also precludes metrisability.  $\square$

*Yet Another Proof.* As for the Egorov example, the form of the projective Weyl curvature (2.31) conflicts with Lemma 2.5 to provide yet another proof. This time  $V^ab{}_c$  has the form  $X^{ab}Y_c$  for non-zero  $X^{ab}$  and  $Y_a$  (with  $X^{ab}$  symmetric but never simple). Lowering the indices with the purported metric gives  $V_{(abc)} = X_{(ab}Y_{c)} \neq 0$ , contrary to (2.29).  $\square$

Finally, we remark that, although the Weyl tensor  $V^ab{}_c$  for the Newtonian structure does not have the form required by Lemma 2.5, it can still be written as

$$V^ab{}_c = 2R^{d(a}g^{b)e}\epsilon_{edc}, \quad \text{where} \quad R^{ab} = -\frac{1}{2} \begin{bmatrix} \partial_1 \partial_1 f & \partial_1 \partial_2 f & 0 \\ \partial_2 \partial_1 f & \partial_2 \partial_2 f & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{and} \quad g^{ab} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

which is of the required form save for  $g^{ab}$  being degenerate.

**2.5. A Weyl metrisable but not metrisable projective structure.** Recall that a Weyl structure on  $M$  consists of a conformal structure  $[g]$  together with a torsion-free connection  $D$  that is compatible with the conformal structure in a sense that

$$Dg = \omega \otimes g$$

for  $g \in [g]$  and some 1-form  $\omega$ , this compatibility condition being invariant under the transformation

$$g \mapsto \hat{g} \equiv \Theta^2 g, \quad \omega \mapsto \omega + 2d(\ln \Theta), \quad (2.32)$$

where  $\Theta$  is a non-zero function on  $M$ . For any metric  $g$  in the conformal class, the 1-form  $\omega$  determines the connection  $D$ .

Consider a Lorentzian Weyl structure on the three-dimensional Heisenberg group [23]

$$g = (dx^1)^2 - (dx^2)^2 + (dx^3 - x^1 dx^2)^2, \quad \omega = 2(dx^3 - x^1 dx^2).$$

This Weyl structure is Einstein–Weyl: the symmetrised Ricci tensor of  $D$  is proportional to  $g$ . Let  $[D]$  be the projective structure defined by  $D$ .

We find that the obstruction  $Q_{ab}{}^c$  from Theorem 1.3 does not vanish. For example,  $Q_{22}{}^1 = x^1$ . The determinant  $T$  from Theorem 1.1 also does not vanish. A convenient way to present  $T$  is to regard it as a ternary sextic. Setting  $X_a = (X, Y, Z)$  we find

$$X_a X_b X_c X_d X_e X_f T^{abcdef} = Z^2 (X + Y + Zx^1)^2 (X - Y - Zx^1)^2$$

up to a non-zero multiplicative constant.

From either of these obstructions, we therefore conclude that the projective structure  $[D]$  is not metrisable. It is nevertheless Weyl metrisable by construction. In dimension two all projective structures are locally Weyl metrisable [20]. We expect this not to be the case in dimension three, where, up to diffeomorphism, a general real-analytic projective structure depends on 12 arbitrary functions of 3 variables, but a Weyl structure only depends on 5 such functions. Characterising projective connections that are Weyl metrisable is an interesting open problem, which we do not pursue here. In general, we also do not know which Weyl metrisable structures are genuinely metrisable. If the Einstein–Weyl equations hold, however, then we have a satisfactory answer as follows.

**2.6. Einstein–Weyl projective structures.** Consider a 3-dimensional Weyl structure  $(D, [g])$  as outlined at the beginning of the previous section. In general, the Ricci tensor of  $D$  contains both symmetric and skew parts, the latter being proportional to  $\nabla_{[a}\omega_{b]}$ . The 2-form  $F_{ab} \equiv \nabla_{[a}\omega_{b]}$  is an invariant of the Weyl structure, often called the *Faraday form*. The Weyl structure is called *Einstein–Weyl* if

$$\Phi_{ab} = 0, \quad (2.33)$$

where  $\Phi_{ab}$  is the symmetrised trace-free part of the Ricci tensor of  $D$  (noting that removing the trace of a symmetric tensor depends only on the conformal class  $[g]$ ).

**Theorem 2.11.** *Let  $(D, [g])$  be an Einstein–Weyl structure in dimension 3, and let  $[D]$  be the projective structure defined by  $D$ . Then  $[D]$  is metrisable if and only if its Faraday form  $F_{ab}$  vanishes.*

*Proof.* Let  $V^{ab}{}_c$  be as usual (1.1). A straightforward but cumbersome calculation yields

$$V^{ab}{}_c = 2\Phi^{d(a}\epsilon^{b)}{}_{dc} - \frac{1}{2}\delta_c^{(a}f^{b)} + g^{ab}f_c,$$

where  $f^a$  is the vector field defined by

$$F_{ab} = \epsilon_{abc}f^c,$$

and indices are lowered and raised by any representative metric  $g_{ab}$  from the conformal class and its inverse  $g^{ab}$ . An even more cumbersome calculation gives

$$Q_{ab}{}^c = \Phi_{ab} f^c + 2\Phi^c{}_{(a} f_{b)} - 2\delta^c{}_{(a} \Phi^d{}_{b)} f_d + 2g_{ab} \Phi^{cd} f_d + f_{(a} \epsilon_{b)d}{}^c f^d,$$

where  $Q_{ab}{}^c$  is our usual quadratic obstruction (1.5) to metrisability. If the Einstein–Weyl equations (2.33) hold then  $Q_{ab}{}^c$  vanishes if and only if  $f^a = 0$ , which happens if and only if  $\omega$  is locally a gradient. But in this case the Weyl connection is the Levi-Civita connection of a conformally rescaled metric  $\hat{g}$ , so it is metrisable (as it is metric).  $\square$

In fact, if the Faraday form vanishes, and locally we choose a metric connection in the projective class according to (2.32), then the Einstein–Weyl equations (2.33) revert to the Einstein equations. Since we are in 3 dimensions, the Einstein equations imply that the metric is constant curvature. Therefore, the only metrisable Einstein–Weyl structures in 3 dimensions are projectively flat.

### 3. PATH GEOMETRIES AND SYSTEMS OF ODES

A convenient way to exhibit examples of projective structures on  $U^{\text{open}} \subseteq \mathbb{R}^3$  is to use an equivalent definition of a path geometry in 3 dimensions as an equivalence class of systems of two second order ordinary differential equations [6]

$$y'' = F(x, y, z, y', z'), \quad z'' = G(x, y, z, y', z'), \quad (3.34)$$

where two systems are regarded as equivalent if they can be mapped into each other by a change of dependent and independent variables  $(x, y, z) \mapsto (\bar{x}(x, y, z), \bar{y}(x, y, z), \bar{z}(x, y, z))$ . An integral curve of (3.34) is, for sufficiently regular functions  $F, G$ , specified uniquely by a point and a direction in  $U$ .

It is relatively straightforward to characterise 2nd order systems (3.34) that give rise to projective path geometries [5, 12]: set  $y^i = (y, z)$ ,  $p^i = (y', z')$  and  $F^i = (F, G)$ , where the indices  $i, j, k, \dots$  take values 2, 3. The necessary and sufficient conditions for the integral curves of (3.34) to be unparametrised geodesics of a torsion-free connection on  $TU$  are [12]

$$S^i{}_{(jkl)} = 0, \quad \text{where} \quad S^i{}_{jkl} = \frac{\partial^3 F^i}{\partial p^j \partial p^k \partial p^l} - \frac{3}{4} \frac{\partial^3 F^m}{\partial p^m \partial p^j \partial p^k} \delta_l^i. \quad (3.35)$$

To establish this result it is enough to consider the geodesic equations for a given  $\nabla$ , and eliminate the affine parameter  $s$  between the three equations

$$\frac{d^2 x^a}{ds^2} + \Gamma_{bc}{}^a \frac{dx^b}{ds} \frac{dx^c}{ds} = 0,$$

where  $x^a = (x, y, z)$ . This yields (3.34), with

$$F^i = A_{jk} p^i p^j p^k + B^i{}_{jk} p^j p^k + C^i{}_j p^j + D^i, \quad (3.36)$$

where

$$A_{ij} = \Gamma_{ij}{}^1, \quad B^i{}_{jk} = 2\Gamma_{1(j}{}^1 \delta_{k)}{}^i - \Gamma_{jk}{}^i, \quad C^i{}_j = \Gamma_{11}{}^1 \delta_j^i - 2\Gamma_{1j}{}^i, \quad D^i = -\Gamma_{11}{}^i.$$

Note that the expressions for  $A, B, C, D$  are invariant under (2.6). Conversely, imposing (3.35) on system (3.34) yields (3.36) as in [5]. For example the Egorov projective structure (2.26) corresponds to a system

$$y'' = 2y(y')^2 z', \quad z'' = 2yy'(z')^2.$$

Expressing any of the projective invariants in this article, such as (1.4), in terms of  $F, G$ , and their derivatives gives point invariants of system (3.34).
